Dr. David Smith died on April 4th, in his seventieth year, at his residence, 1, Westbourne-terrace, Glasgow, after a brief illness. He was born at Ochiltree in Ayrshire and studied medicine at the Universities of Glasgow and St. Andrews, where he was noted for diligence and gained several prizes. In 1858 he took the diploma of M.R.C.S. Eng. and in 1861 he graduated as M.D. at St. Andrews. Soon after becoming qualified he was appointed demonstrator and assistant to Dr. William Mackenzie of Glasgow, author of "A Practical Treatise on Diseases of the Eye" and various other ophthalmological works. Dr. Smith practically spent all his life in Glasgow. He remained with Dr. Mackenzie about seven years, after which he engaged in general practice for some time, but for the last 20 years he devoted himself to ophthalmic work. In 1868 and 1869 he contributed to THE LANCET a series of six lengthy articles on the "Structure of the Adult Human Vitreous Humour." He also wrote a treatise on "The Preservation of Sight," published in 1871. Dr. Smith was much esteemed by all who knew him alike for his professional ability and for the sincerity of his character.

DAVID STEELE MOON, L.R.C.P., L.R.C.S. EDIN.

Mr. David Steele Moon of Dundee died in that city on April 8th after an illness extending over more than a year. He was a native of Liff, near Dundee, and received his professional education at Anderson's College in Glasgow. In 1869 he took the diplomas of L.R.C.P. and L.R.C.S. Edin. which enabled him to hold appointments as house surgeon first in the Glasgow Royal Infirmary and afterwards in the Dundee Royal Infirmary. More than 30 years ago he commenced practice in Dundee, succeeding the late Dr. Begg, whose daughter he married. He soon acquired a high reputation and was greatly esteemed by a large circle of patients for his professional skill and sympathetic devotion to their interests. He gave special attention to surgery and for a period of years was one of the surgeons to the Dundee Royal Infirmary. On the expiry of his term of office he was placed on the consulting staff. He was a zealous member of the local medical society and frequently took part in its discussions. By his professional brethren he was held in high respect because of his rectitude and his invariably genial and sunny disposition. He leaves a widow and one son who is engaged in the study of medicine.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Georg Meissner, formerly professor of physiology in the University of Göttingen, at the age of 75 years. His name is well known in connexion with the "tactile corpuscles."—Dr. Ludwig Glaevecke, titular professor and *privat-docent* of gynæcology in the University of Kiel, at the age of 50 years, suddenly while on a visit to his birthplace, Rostock.—Dr. T. Bornhaupt, professor of surgery in the University of Kieff.

Medical News.

UNIVERSITY OF EDINBURGH.—The following is the official list of passes at the recent professional examinations for degrees in medicine and surgery:—

First Professional Examination.—J. R. Adam, Janet Armstrong, Annie C. Austin, Alice E. M. Babington, G. L. Batra, A. E. C. Beausoleil, W. M. Biden, V. V. Blake, T. C. Borthwick, A. M. Bose, T. S. Bradburn (with distinction), W. G. Brand, F. A. J. Brodziak, B. S. Browne, J. E. Brydon, W. F. Buist, A. W. Burton (with distinction), J. A. Campbell (with distinction), H. G. Carter, L. L. Cassidy, John Cathcart, H. A. Cookson, N. A. Coward, J. S. Crichton, G. C. Dalton, F. A. Duffield, W. J. Duncan, G. F. Fismer, Helen Forbes, E. L. Galletly, C. F. C. Galloway, W. T. Gardiner, P. K. Ghosh, H. R. B. Gibson, R. L. Girdwood, M.A., W. E. Goss, D. M. Grant, W. B. Grant, F. W. Greaves, J. A. W. Hackett, A. G. Hamilton, Julia V. Henslow, G. de C. Hugo, Herbert Hutson, W. C. Jardine, W. D. S. Johnston, J. H. Jones, S. A. Karim, Lina Kurz, James Langwill, J. H. Lawry, L. A. Lewis, Harry Lipetz, H. A. V. Loots, P. C. Lornie, J. C. Lorraine, H. F. Lumsden, D. C. Macaskill, M.A., J. C. MacCallum, J. R. M'Gregor, G. E. G. Mackay (with distinction), Alex. S. Mackenzie, Arch. D. M'Kensie, J. T. Mackenzie, A. C. M'Killop, Duncan Mackinnon, A. G. MacLeod, Andrew M'Nair, Donald M'Phail, R. C. MacQueen,

A. J. Macvie, A. C. Mallace, M.A., W. M. Menzies, E. L. Middleton, A. F. Miller, L. M. V. Mitchell, J. B. de W. Molony, Flora Morrison, J. A. Mortimer, N. S. Neill, W. J. Nisbet, E. F. W. Nixey, H. LONDON SCHOOL OF TROPICAL MEDICINE (UNIVERSITY OF LONDON).—Of the students of the above school who presented themselves for the examination in April, 1905, the following have passed:—

*Dr. H. Ludovici (Colonial Service), *Dr. F. B. Thompson (Colonial Service), *Miss H. B. Hanson, M.D., Miss E. Watts, Dr. R. F. William (Colonial Service), Dr. H. A. Foy, Miss M. E. Hayes, M.B., and Dr. R. van Someren.

* Passed with distinction.

MEDICAL MAGISTRATE.—Alderman S. E Johnson, L.S.A. Lond., L R.C.S. Edin., has been enrolled on the commission of the peace for Worcester.

DONATIONS AND BEQUESTS.—By the will of Mr. Luther Holden, F.R.C.S., St. Bartholomew's Hospital will receive £3000 to found and to endow a Luther Holden Scholarship in surgery and £500 for the rebuilding fund Miss Sleigh, "Sister President" at St. Bartholomew's Hospital, will receive £100. The testator also left a sum of £10,000, subject to his wife's life interest, as to one-half for the Samaritan Fund of St. Bartholomew's Hospital.

AMBIDEXTERITY FROM THE SURGEON'S POINT OF VIEW.—On April 13th, at the rooms of the Royal Statistical Society, Adelphi-terrace, Strand, W.C., Mr. E. Noble Smith delivered the fourth of the series of lectures for the session 1905 to the members of the Ambidextral Cultural Society, of which he is President. There could be no doubt, he said, that the left hand had been very much neglected and it would be an advantage to train that hand equally with the right. The aim of the society, however, should be to teach dexterity as well as ambidexterity. Ambidexterity was of great use to the surgeon who might at any time be called upon to use either hand. In warfare a surgeon might be suddenly deprived of his right hand and it would be an enormous advantage to him if he had already learned to use his left. General Baden Powell, who was a great advocate of ambidexterity, had stated that a soldier is not properly trained until he can use his left hand as well as his right. He (the lecturer) was of opinion that by training the left hand the power of using the right was also developed to a greater degree and he gave several examples to show that not only our manual abilities but our senses also were not trained to their full capacity. The general use of the right hand in preference to the left was probably responsible for a large number of cases of spinal curvature. In 200 cases of dorsal curvature of the spine which he had examined the curve to the right was present more than twice as frequently as the curve to the left and in an examination of 118 cases he found the proportion to be 5 to 1. In the large majority of cases of curvature to the left there were special contributing causes—such as wry neck, short leg, and so forth. A French surgeon had found the proportion in 1000 cases to be 7 to 1. Special desks should be provided for children at school and he advocated the use of a couch that children might read in the prone position. In conclusion, he hoped that the time would come when the bodies of scholars would be as liberally provided for as were their minds. The society was doing a good and useful work and it ought to receive the support of the public who were invited to become members. The first of the series of lectures, Ambidexterity in Music, by Professor W. H. Cummings, which was delivered in February last at the Guildhall School of Music, will be repeated with additional illustrations and artists at the Erard Rooms, Great Marlborough-street, during the month of May.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Vivisection.

Mr. TOMKINSON had a motion on the paper on the evening of Wednesday, April 12th, about the rules governing the practice of vivisection, but the Home Rule debate blocked the way and the matter had to be deferred till a more convenient opportunity, which probably will not occur in the life of this parliament. Had Mr. Tomkinson obtained the ear of the House he would have moved: "That this House is of opinion that the rules governing the practice of vivisection are confusing and contradictory in their tenour, have wholly failed to secure to animals that immunity from pain they were designed to afford, and urgently require revision; and that, as no rules can be devised to effect this object, the practice of vivisection should be wholly prohibited."

Lunacy Bill.

The ATTORNEY GENERAL for England has reintroduced the Bill to amend the Lunacy Acts which he brought in at the end of last session as a result of the debate on the subject which was initiated by Sir JOHN BATTY TUKE.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 12TH.

the attention of
Member. I may

add that 19 additional cases were notified during the week ended on April 8th and I am in communication with the town council as to the circumstances which led to their occurrence.

Sir Walter Foster further asked the President of the Local Govern- [illegible] ast few years the Bradford guardians [illegible] ications for out-relief, and whether [illegible] for medical out-relief by requiring [illegible] on) to attend before the board or a committee, or by making the relief on loan in the first instance, or by other means; and, if so, whether he would send a communication to the guardians recommending them to encourage applications for medical out-relief (by those unable to pay for medical advice) in the early stages of illness and before infectious diseases have developed.—Mr. Gerald Balfour replied: I am aware that some few years since the Bradford guardians adopted a policy of administration of out-relief the effect of which has been to diminish the number of applications, but I have no information to show that the action of the guardians has been such as to render it necessary or desirable to send to them a com- [illegible] ed to in the latter part of the question.

[illegible] Iome Secretary whether his attention had [illegible] Bradford a coroner and jury were under [illegible] re compelled to view the body of a man [illegible] medical officer, had been suffering from malignant small-pox; and whether, in view of the practice of viewing bodies in such cases becoming a possible danger to the community, he would consider the advisability of again introducing the Bill which in 1879 passed its second reading under the care of the then Home Secretary, the object of which was to make the viewing of bodies by coroners and juries no longer compulsory.—Mr. Akers Douglas replied: My attention has not been called to the case mentioned by the honourable Member. With regard to the general question I fear that I cannot add anything to an answer on the same subject which I gave on March 23rd.—Mr. MacNeill asked whether it was not the case that many coroners were opposed to the viewing of bodies.—Mr. Akers-Douglas said: A great many coroners are opposed to the practice of viewing bodies but until I have made further inquiries I am not inclined to introduce a Bill.

THURSDAY, APRIL 13TH.

Litigation with a Medical Officer.

Mr. Cathcart Wason asked the Lord Advocate whether he was aware that the legal expenses incurred by the Durness parish council by its litigation with the parish medical officer had been put upon the parish rates, and whether, seeing that those ratepayers who jointly paid more than two-thirds of the parish rates protested against the action of the chairman and two members of the parish council which led to these legal expenses being incurred, he would say whether the Local Government Board for Scotland had sanctioned the placing of these legal expenses upon the parish rates.—The Lord Advocate answered: I am informed that the Local Government Board has not sanctioned the expenses incurred by this parish council.

The Deportation of Insane Paupers.

Mr. Gilhooly asked the Chief Secretary for Ireland whether he had received a resolution, passed unanimously by the committee of management of the Cork District Lunatic Asylum, calling on him to promote a Bill to enable the committee to deport insane patients of other nationalities and counties who had been committed and remained chargeable to the local rates and pointing out that those patients occupied the places in the institution erected, maintained, and taxed for local patients, thereby contributing to the overcrowding which at present existed in the asylum; and, if so, whether he proposed to give effect to it during this session.—Mr. Long answered: The resolution has been received. I am unable at present to give an undertaking to introduce legislation on the subject.

MONDAY, APRIL 17TH.

Appointment of Highland Medical Officer.

Mr. Weir asked the Lord Advocate whether, in view of the extent of the area of the mainland of the combined counties of Ross and Cromarty and Inverness-shire, he would state whether the proposal to appoint one [illegible] unties had receive [illegible] tland. —The Lor [illegible] es not favour the [illegible]

Alleged Discontent in the Royal Army Medical Corps.

Dr. E. C. Thompson asked the Secretary of State for War whether he [illegible] existing among [illegible] Medical Corps [illegible] Secretary of State [illegible] nany of the members of the board were civil [illegible] ad no personal knowledge of the qualifications [illegible] recently passed over, and were obliged to take their opinion of these officers from others junior to themselves, and that the continuance of the existing system threw the responsibility of promotions from the Secretary of State and the Director-General on the Advisory Board, he would arrange that in future officers passed over with excellent official records would be informed of the reason for their supersession.—Mr. Arnold Forster replied: The honourable Member raised last session the points now brought forward again and definite answers were given to each. I have nothing to add to the answers which I then gave him and I am not aware of the dissatisfaction.

REGISTRATION OF NURSES: EVIDENCE BEFORE SELECT COMMITTEE.

The Select Committee of the House of Commons which has been re-appointed this session to consider the expediency of providing for the registration of nurses commenced the hearing of evidence on April 12th. Mr. H. J. Tennant was in the chair.

Miss Forrest of the Victoria and Bournemouth Nursing Institute and Home Hospital, replying to Mr. Charles Hobhouse, in the temporary absence of the chairman, said she was in favour of a system of State registration. Her position as head of what she believed to be the largest private provincial nursing institute brought to her notice two points, both of which would be lessened, if not entirely obviated, by State registration. On was the great difficulty in discovering what each nurse knew before engaging her, owing to the different standards in different hospitals, the different standards existing at the same hospital at different times or if the officials were changed, or the absolute want of standard. There was also the difficulty of tracing nurses, no register being kept. She had control over 160 nurses resident in four institutions, and they were sent over the south and west of England and also to the Continent. A three years' training was necessary in the case of the nurses she engaged. That rule had been broken once or twice in respect of nurses whom she knew. She expe [illegible] btaining information about nurses who appli [illegible] umber for her needs. As to the different [illegible] hospitals, everything was taught in a hospital if the matron was good and cared for her duties. If not, the teaching went to the wall. Three years was a safe minimum for general training in a hospital of 50 beds if the training was good. She wished to remedy the want of standard by State registration, under which the committee would be bound to see that the matron brought her nurses up to the standard. The central board would set the examination and if the nurses of a hospital passed that examination as a rule, they would know that that hospital gave a proper training, but if the great majority failed they would know that a proper training was not given. She did not think the expenses of training for three years at hospitals were very great. Last year 460 nurses, so-called, applied to her and she took all whom she thought were properly trained and these numbered 65. Nurses who had not been trained or were only half-trained practised a good deal. The number of untrained nurses practising in Bournemouth was large.

Replying to Dr. C. F. Hutchinson, the witness said she herself ran the institution she had been speaking of; it was her private property; it was not inspected or registered.

You have no committee to be responsible to? You employ the nurses as you like and make any arrangement [illegible] your sole will and control?—I do not [illegible] so far as being on my staff is concern [illegible] were audited every six months by a chartered accountant but they were not published. She was responsible only to herself. She thought it would be a very good thing if institutions were registered. There were other institutions not so well known as her own the registration of which would be for the protection of the public and the nurses.

Have you had much trouble as to the inefficiency or want of character of nurses?—Not a great deal, but I have had trouble in getting good nurses.

In the case of a nurse who works on her own account, are not the public protected from fraud because she is not employed except on the recommendation of a medical man or a friend?—I do not know.

So that if a nurse is incompetent she would very soon be found out and would retire? I want to draw out from yo [illegible] between those nurses and the nurses of your instituti [illegible] A large number have got a home and they are [illegible] certain number of them are incompetent. She knew of a monthly nurse whom the medical attendant tried to get rid of but the people would not give her up. Fortunately for the patient and the medical man this nurse fell down and broke her arm. When they then got a trained nurse the people knew the difference and understood why the medical man was so anxious to get her.

But those people who are on their own account have to make their living on their character and ability as nurses, so that the result would be that a nurse not competent would drop out?—No, they have not done so.

In reply to Mr. Douglas Miss Forrest said that she would have the central board appoint a body of experts to examine nurses. She stated in illustration of her evidence that her nephew had been in a nursing home undergoing a very serious operation and that his night nurse was the parlourmaid of the day before.

Answering the Chairman, she could not give direct evidence of cases of scandal and immorality. She could not go into private houses to see how nurses were getting on and she could not send a Government inspector after them. She would like to have State registration with the object of seeing that nurses were women of sufficient knowledge and properly equipped before attending private cases. She did not think there would be any danger of the wrong kind of women being registered for all time under State registration.

Mr. Charles Hobhouse: Would you make the removal from the State register consequent upon the loss of moral character or upon the loss of nursing proficiency?—I think certainly on the loss of moral character and in certain circumstances for the loss of efficiency, for that might mean the life of another person

Replying to Sir John Batty Tuke the witness said that the examination must be to a certain extent theoretical. The nurses must be able to state what symptoms to watch for and to show knowledge as to bed-making and certain things which nurses must do. She did not admit that that would degenerate into mere routine. The registration fee might be two guineas but she thought one guinea would be enough.

The Chairman asked whether the witness saw any fundamental objection to having two classes of nurses—one perhaps on three years' training and the other with one year's training.

Miss Forrest said she did not think there was any fundamental objection but it would lead inevitably to confusion and the public would not be able to distinguish the one from the other.

The Chairman instanced the case of a woman who had had some nursing experience going into a house and cooking the meals and helping generally in the house and asked whether the witness would exclude her from the register.

Miss Forrest replied that she would exclude those women from the register as qualified certificated nurses but she would be quite willing that they should have some kind of registration because they performed a very useful service. They might be registered as cottage helps or nurses' helps.

Sir John Tuke: They are very much more than that. In many cases they actually perform the duties of a nurse. In the West Highlands of Scotland they are essentially nurses.

Mr. Charles Hobhouse said he understood that the committee would at future s [illegible] on this particular point which would bear [illegible] hn Tuke had just said.

Miss E. [illegible] n reply to the Chairman, that she was trained at the London Temperance Hospital and had been engaged at the Middlesex Hospital, St. George's Hospital, Beirut, where she acted as lady superintendent

profession which required education and brain work. Nurses would make a sacrifice and pay a fee of five guineas. The nursing profession ought not to be on a low level. If nursing were made a more dignified profession there would be a sufficiency of candidates to supply the demand. They ought to try for a higher standard. She would have as the first standard the fully trained nurse and another standard for those who were to be teachers and

Would that not confine the field of candidates?—I do not think so. Once the profession was

pleasure in studying for

Answering Sir JOHN TUKE she said it was her opinion that they could have security for the standard of training

for what the e as perfect as possible was not against ignorance but against the great outcry against nurses women themselves The best method of eliminating inefficiency was by producing as many nurses as possible of a better type. The inefficient ones would have no chance when they did that. Many nurses who were trained went home or got married and there was a great wastage among the best class of nurses. She admitted that there were a good many bad nurses but not so many as was represented. In ten years the London Hospital granted 796 certificates and turned out 619 certificated and qualified nurses who left during that period. Of these 136 left for home or other purposes so that out of 619 only 483 were provided for the use of the public outside. She could not agree with a previous witness

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE HEALTH AND MORALITY OF THE PITCAIRN ISLANDERS.

Mr. R. T. Simons, who last year was instructed by the High Commissioner for the Western Pacific to inquire into the state of affairs in Pitcairn Island, in the South Pacific, where the mutineers of the *Bounty* were landed to take their chance in 1790, has made a report in *which the following* passages occur —

> "The Pitcairn islanders number 77 males and 92 females, including children and infants, of whom 68 males and 73 females are now resident on the island. They are a hard-working people, more or less healthy, exhibiting certain vicious tendencies which religion has been unable to eradicate Many of them are narrow-minded and unstable. They have adopted an extraordinary patois (derived from the language of the Tahitian women who accompanied the mutineers of the *Bounty* to Pitcairn Island) which is employed in conversation among themselves, although most of the adults can speak the English language fairly well—in some instances very well, considering their circumstances and environment There are persons of ability among them, but a few appear to be lacking in intelligence. The children and young people are *numerous and, if properly cared for, should turn out useful* members of the community
>
> With regard to the morals of the islanders, in the aggregate I fear I can say little in their favour. Fornication, adultery, illegitimate children, petty thefts, brawls, bad language, &c, are faults among them (happily they do not use intoxicants) and it was disquieting to learn that the laws and regulations dealing with those offences had seldom been enforced. Indeed, the general laxity has been so great, that abortion by means of drugs and instruments of local contrivance was not of infrequent occurrence I have made provision for the punishment of that and of other crimes in the future.
>
> On arrival at Mangareva, on my way to Pitcairn, the administrator of the Gambiers, a gentleman born and educated in the Island of Mauritius, who is also in medical charge of the islands under his administrative control, mentioned to me that during the past two years many of the Pitcairn women and girls had visited Mangareva, where venereal diseases are prevalent, and that, in consequence, he feared that some of them had contracted those complaints and had introduced them into their island. Dr. Cassian further expressed his interest in the Pitcairn Island community and generously proffered his medical services without remuneration, provided that those afflicted would go up to him for treatment Accordingly, having ascertained after my arrival at *Pitcairn that a few* such cases were existent on the island, I made known Dr Cassian's kindly proposal and invited the sufferers to accompany me back to Mangareva None, however, responded to my appeal and I can only surmise that the persons in question have preferred to go up in the cutter. I also found at *Pitcairn Island consumption,* lupus, glandular swellings, asthma, and various forms of skin disease These cases will likewise be taken in hand
>
> and it is to be ho
>
> fail to take advan
>
> their welfare I
>
> the front teeth of most of them are bad, the only visible result of their intermarriage with each other
>
> Some years ago the Pitcairn Island community embraced the faith of the Seventh Day Adventists, a religious sect having its origin [illegible]
>
> [illegible] stories and exclamations and *obscene songs are not unknown to* them, and it is an alleged fact that on suitable occasions women will accompany the men on board passing ships ostensibly to sell curios, but in reality for immoral purposes. The Pitcairn people contribute 10 per cent of their produce and of any moneys they may receive as a tithe to *the Church, and they pay subscriptions to* the Sabbath school and other religious funds"

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—In the *London Magazine* for March is an eight page advertisement of the O Connor Extension Company, entitled "Life's Handicap," by a Fellow of the Royal College of Surgeons In the text my name is [illegible] Will you permit me to state that I am not

ve a letter from the managing

l not be used in such a manner

I am, Sirs, yours faithfully,

Bedford square, W C. CHISHOLM WILLIAMS, F.R.C S Edin

MISCELLANEA.

We are often asked by our readers for advice on the merits of certain articles and firms, and the task of giving such advice is obviously an invidious one. It is for this reason that we mention in brief some catalogues which have recently reached us and appliances to which our attention has been directed, leaving it to the individual to select from them as he may require.

Messrs. Brady and Martin, Limited, Newcastle-on-Tyne, issue a price list which contains, in addition to a useful drug catalogue, illustrations and prices of microscopes, electrical appliances and apparatus, surgical instruments, hospital furniture, and modern appliances required in the practice of medicine and surgery. It consists of 207 pages and will be found to be a convenient work of reference for many members of the medical profession.

A catalogue issued by Messrs. C. A. Hoefftcke, Limited, Woodstock-street, London, W., contains illustrations and descriptions of a large number of appliances used in orthopædic practice. It is not intended to be a complete list but many appliances are described for use in fractures, hip disease, diseases of the knee, and paralysis, scoliosis, kyphosis, and spondylitis. A section is also devoted to apparatus for active and passive movement for working stiffened joints. Some special surgical instruments are also described.

Messrs. W. Martindale, New Cavendish-street, London, W., publish a complete catalogue of their drugs and a price list which includes in addition to surgical appliances reagents and stains for microscopic work, chemical and bacteriological apparatus, and photographic chemicals. It consists of 216 pages.

The catalogue of Messrs. Maw, Son, and Sons, Aldersgate-street, London, E.C., containing 507 pages, is divided into nearly 60 sections and embraces almost everything that a medical man may require in his profession. The index occupies 36 pages and nearly every article catalogued is illustrated. To enumerate even a small proportion of the articles sold by this firm would be impossible in the space at our disposal and it must suffice to say that the firm is prepared to equip in instruments and appliances the smallest surgery or the largest hospital. The section on "Sterilisation of Urethral Instruments" contains illustrations of several apparatus of useful and novel design.

Messrs. Heal and Son, Tottenham-court-road, London, W., publish an illustrated catalogue of furniture—beds, tables, lockers, and so forth—for use in hospitals and private sick rooms. A bed for epileptic patients which this firm has supplied to several lunatic asylums is a useful one and the same may be said of the "labour bedstead" which has been supplied to Queen Charlotte's Hospital. The head- and foot-rails are made exceptionally strong and are removeable, while there is a loose wooden bottom which can be used as a stretcher.

Messrs. Maple and Co., Tottenham-court-road, London, W., call our attention to their completely equipped nurseries and exhibition of nursery furniture now on view at their showrooms. The walls of the nurseries are decorated in bold and simple designs, illustrating in many cases well-known nursery rhymes, while the furniture, which in some cases has moral maxims painted upon it, is exactly suited to the heights of the children for whom it is designed. All corners are rounded off as a precaution against children injuring themselves. The walls are washable and the top panels of the room doors open inwards for the purpose of giving free ventilation, the air passing above the heads of the children to the windows. From a hygienic no less than from an educational point of view this exhibit is much to be commended.

THE "S" WRAP UNDERGARMENT.

We have received from Messrs. John Smedley, Limited, of Lea Mills, Matlock, a specimen of underclothing designed especially for ladies' wear. The material is all wool, is said to be unshrinkable, and is known as the Jay finish. By Jay finish is meant a finishing process which prevents the fabric from "felting" or casting fluff. This quality of woollen garments is a frequent source of annoyance. The special feature of the garment is, however, the "S" flap at the back which gives complete protection to those parts of the body which are not protected by the ordinary combinations. Moreover, the extra length in the back given by the gusset prevents the garment from dragging when the wearer assumes the sitting posture. Buttons are not necessary. The same manufacturers make a "star" seating in the pants and the drawers worn by men. There are thus no seams at the fork to split or to give rise to chafing. Like the "S" wrap undergarment the patent star seat permits free and comfortable movement.

AN EMERGENCY LIGHT.

Apropos of a paragraph which appeared in The Lancet of April 1st, p. 897, on the occasional failure of the electric light-supply, our attention has been drawn to an apparatus designed by Mr. H. McGillivray of Matfen-place, Wingrove, Newcastle-on-Tyne, which automatically switches on emergency lights in the case of electric cars when the line current fails or the trolley slips the wire. The apparatus consists of a battery and automatic switch. The battery (8-cell) is placed underneath the car seat and an electro-magnet or solenoid, which controls a cut-out in the auxiliary lamp circuit, is fixed at the end of the car. The battery is charged automatically from the ordinary car-lighting circuit in series with the lamps and as occasion demands supplies in its turn current to the lamps in the car. It is stated that this apparatus is giving very satisfactory results on the electric cars in Newcastle and we understand that the system has been tested on the "tube" with equal success. There is always some uncertainty about the current for domestic supply, public buildings, &c., being maintained without a break, and the failure of the light is a source of great inconvenience and may easily give rise to alarming consequences. This system of emergency lighting is calculated therefore to remove a serious disadvantage of electric lighting and it may easily be applied, it is stated, to the installation of the house, the theatre, the shop, and so on.

MANNERS IN THE LONDON STREETS.

To the Editors of The Lancet.

Sirs,—Do you not think that much of the confusion on the sidewalks of the streets has arisen from the disappearance of the old notices from the lamp-posts "Foot passengers keep to the right"? Those of us who remember the passengers of, say, 30 years ago will recall how, as a matter of course, each took his proper side on meeting. Now that so many ride bicycles they have learned to keep to the left on the roadway and naturally do the same on the pavement. Others trained in the old fashion keep to the right and there is constant confusion.

The custom of driving and riding on the left side of the road is said to have arisen at the time when everyone who approached was a possible enemy and hence it was advisable to have the sword hand towards him. In the same way one kept to the right on the sidewalk so as to have the sword-hand free in case of being jostled or incommoded by one coming in the opposite direction.

On the continent, where everyone rides and drives on the right of the road, it is proper that he should keep to the right when on the pavement. In the British Isles, where one must conform to the usage of keeping to the left on the roadway, it would seem that the time has come to adopt the same practice on foot. I have often wished that notices could be posted everywhere "Keep to the left."

I am, Sirs, yours faithfully,

April 18th, 1905. Observer.

MINERS AND TYPHOID FEVER.

It appears that at Ashington, the largest coal-mining district in Northumberland, miners and their families are much more subject to typhoid fever than are the workers above ground and their families. It is said that there are twice as many working above ground as below and yet the proportion attacked is nine miners or members of their families to every one person employed above ground. Taking the underground workers alone and comparing them with those working above ground, without reckoning their families, the proportion is 17 to one in favour of the surface men and with the wives and children it is six and seven to one respectively. The men in the mines are said to drink the same water as do those above ground. There is evidently room for sanitation.

A NEW VENTILATING SASH FASTENER.

Messrs. W. and T. Avery, Limited, of the Soho Foundry in Birmingham, have sent us a specimen of the "Lorie" No. 1 reversible ventilating sash fastener, by the use of which ordinary windows may be left open for some distance at either the top or the bottom without risk of intruders entering. A bolt, which is in reality a quick-acting screw working in an adjustable split nut, is fixed on the top bar or rail of the bottom sash close to one side of the window-frame and the end of this bolt when forced outwards presses against a metal plate fastened to the vertical side of the upper sash. If the window is partly opened before the bolt is forced out the two sashes will be securely fixed in this position until the bolt is slackened by some one inside the house. The disagreeable rattling of a window can also be effectually prevented in the same way.

◆

Ethics has asked us a puzzling question. In our view B can remain in attendance upon C without a breach of ethics, but the reverse has been maintained. We propose to return to the subject.

Communications not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Irish Times, Reading Mercury, Literary Digest (New York), Scientific American, Mining Journal, Standard, Western Mail (Cardiff), Aberdeen Weekly Free Press, Freeman's Journal, Hertfordshire Mercury, Windsor and Eton Express, Guernsey Star, Pall Mall Gazette, Belfast Whig, Halifax Courier, Belfast News Letter, Liverpool Post and Mercury, Daily Chronicle, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. F. L. Anderson, Lond.; Messrs. Allen and Hanburys, Lond.; Dr. J. F. St. J. Annesley, Fermanagh; Messrs. W. and T. Avery, Birmingham; Automatic Disinfectant Delivery Machine Co., Lond., Managing Director of.

B.—Dr. W. C. Bosanquet, Lond.; Banca Commerciale Italiana, Bari; Messrs. Bemrose and Sons, Lond.; Dr. Francis T. Bond, Gloucester; Dr. Baumstark, Homburg; Mr. Frank P. Barker, Lond.; Dr. C. A. Ball, Dublin; Mr. C. Birchall, Liverpool; *Birmingham Daily Post*; Mr. J. W. Benson, Lond.; Mr. J. N. Bencini, Florence; Mr. T. W. Barber, Lond.; Mr. W. H. Brown, Leeds; Mr. A. S. Barling, Lancaster,

C.—Mr. H. A. Collins, Croydon; Messrs. Cassell and Co., Lond.; Mr. L. Carré, Lond.; Messrs. A. H. Cox and Co., Brighton; Mr. G. Candler, Black Torrington; Cheltenham Corporation, Clerk of; Messrs. J. The Lumleian Lectures

ON

NUTRITION AND MALNUTRITION.

Delivered before the Royal College of Physicians of London on March 28th and 30th and April 4th, 1905,

By W. H. ALLCHIN, M.D. Lond., F.R.S. Edin.,
FELLOW AND CENSOR OF THE COLLEGE; SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

LECTURE I.

Delivered on March 28th.

Mr. President, Fellows of the College, and Gentlemen,—I desire at once to express to you, Sir, and to my late colleagues on the Censors' board my high appreciation of the honour done me in being selected to hold the Lumleian lectureship this year. For indeed it is an honour to take a place on the roll of lecturers who since the year 1581 have addressed the College and amongst whom is included the illustrious Harvey who in his Lumleian lectures commencing in 1616 expounded his views on the circulation of the blood. The recollection of this circumstance and of the many great physicians who in more recent times have alike instructed and charmed their hearers from the place which I for the moment occupy, whilst it may stimulate your lecturer to his best endeavours, none the less fills him with fear at the responsibility of his task and furnishes him with a claim for your forbearance and generous consideration. For these in fullest meed do I entreat at your hands.

Definition of Normal Nutrition.

It will be obvious that for a satisfactory treatment of the subject upon which I propose to address you it will be desirable and even necessary that I should commence by considering what it is we understand by the term "nutrition" as a normal process or rather combination of processes. And this is the more incumbent on me since a large amount of work of an experimental character has been carried out by numerous observers in various parts of the world which has contributed to establish a certain accuracy in our conceptions on what is admittedly one of the most difficult problems for investigation and at the same time has suggested further hypotheses that still await verification. Clearly no useful notion can be entertained of what *is to be understood* by "*malnutrition*" until some agreement is arrived at as to what is implied by the normal process, though it may well be that many of the facts observed in those experiments which disease offers may, and undoubtedly do, contribute to the elucidation of the healthy living.

Among the various data which form the basis of biology, whether the study be that of animals or plants, of health or of disease, is the recognition of the fact that the manifestations of life are found to be invariably associated with the presence of a certain peculiar material of variable and highly complex constitution denominated protoplasm, or, better, bioplasm, with the further postulate that every vital process is the outcome of the reaction between this material and its environment; every phenomenon which the living organism presents, be it chemical or physical or of that more peculiar character which we speak of as vital, is the expression of the conversion of potential energy into kinetic energy or the reverse. Numerous and varied as these manifestations are in beings so highly organised as ourselves they are all to be seen in their simplest form in the unicellular organisms that maintain an independent existence and may all be regarded as the outcome of those material interchanges between the constituents of the bioplasm among themselves and with the food-stuffs which are brought into relation with it from outside, whereby *the integrity of the* living matter is upheld and its continued activity rendered possible. To the processes by which the bioplasm assimilates or makes use of this outside material the term "nutrition" is applied and underlying, as it does, the characteristic activities of living matter nutrition may in its widest sense be regarded as synonymous with life itself. It is, however, in a somewhat more restricted sense that I am now employing it—viz., to designate those preparatory changes which the ingesta undergo to fit them for incorporation in the protoplasmic molecule and their ultimate fate therein. The subject, it will be at once seen, deals with certain compositions and decompositions of matter, the formation of more and more complex compounds with their subsequent splitting up into simpler substances. As such it comes within that province of knowledge which we term chemistry, but concerned, as it is, with that form of matter recognised as living t
a sub divis
occupy a r

Clearly,
outset, the bioplasm on the one hand and on the other the food or nutriment, for I leave out of account for the present those portions of the ingesta which are incapable of being made use of by the bioplasm and which are therefore innutritious.

The Bioplasm, its Structure and Composition.

And first as to the bioplasm itself. That this substance, even in the simplest form of it with which we are acquainted, exhibits some degree of structure, some difference in appearance and consistency in different parts, is now all but universally recognised; the view that it is essentially homogeneous in character and that such structural features as it exhibits are the result of post-mortem changes or are actually artifacts is no longer tenable. Of the nature, however, of its structure no little difference of opinion prevails, but as it is in a minor degree that I am now concerned with this aspect of the question it will suffice to say that apart from the obvious separation into cell contents and nucleus which are to be met with in all cells a third structural element known as the central corpuscle or centrosome is to be generally detected. Each of these several constituents of the cell is to be distinguished by easily recognisable differences in the arrangement and appearance of the material of which they are made up. Further, the protoplasm of which the nucleus and mass of the cell are composed exhibits a general appearance of being formed of a more or less distinct reticulum—spongioplasm—the meshes of which are occupied by a semi-fluid substance—hyaloplasm. A similar arrangement obtains in the nucleus, the fibrillar network owing to its behaviour with certain staining reagents being known as the chromatic substance, the clear substance or matrix being termed achromatic Considerable variations are met with in different cells and even in the same cell at different times, marked peculiarities in the disposition of the nuclear fibres appearing previously to the division of the nucleus—mitosis. Doubts have existed as to whether both the network and the hyaloplasm of the cell are living or whether the reticulum alone can be so described. The most recent view, however, of the structure of the protoplasm which shows it to have a "foam-structure," depending "upon the presence within a uniform ground-mass of a large number of extremely fine vacuoles, lying almost at the limits of microscopic visibility and so close together that their walls consist of relatively thin lamellæ,"[1] would seem to suggest that the entire protoplasm is to be looked upon as living matter.

For my present purpose I am more concerned with the chemical composition of the living matter and unfortunately our knowledge of this is much less even than it is of its structural characters. I need not remind you of the fundamental difficulty that meets the investigator—viz., that the very means that are employed for pursuing the inquiry cause the death of the material and consequent elusion of the problem. This much, however, may be affirmed, that invariably there is to be obtained from the bioplasm a certain amount—perhaps as much as 60 per cent.—of those extremely complex bodies termed proteids composed of the five elements. carbon, hydrogen, oxygen, nitrogen, and sulphur, all of them of low atomic weight but combined to form molecules of great size owing to the very large number of atoms of which they consist. Associated with these nitrogenous constituents of the protoplasm there are to be found with varying frequency particles of carbohydrates, of fats, together with *inorganic* salts and water, as well as such substances as urea and purin bodies (xanthin, hypoxanthin, guanin, &c.). Whilst without doubt the proteid constituents are the most important as they are the most abundant, forming in muscle about from 20 per cent. to 25 per cent. solid ter of that tissue, it is by no means probable that it is roteids as we know them that they exist in the bioplasm it may be taken as certain that no one form of matter olely capable of manifesting life, rather is it the oute of interactions among many diverse bodies. This ers it most likely that the other substances mentioned— fats, carbohydrates, and salts—are in varying degree ntial components of the living matter, whether they about to be used by the nitrogenous constituents or the products of decomposition of those nitrogenous conients such as urea and the purin bodies undoubtedly are. eover, it must be remembered that protoplasm is far being of a uniform composition. We are perhaps a too apt in our recognition of the universality of this sical basis of life to assume that it is of constant acter, if, indeed, its actual composition is ever considered. difficulties surrounding the investigation of its chemical cture are such as to offer a barrier to further inquiry and have become so satisfied with the word protoplasm as all cient that we go no further and fail to realise that we are y only on the threshold of the problem. But although re profoundly ignorant of its chemical constitution we nevertheless affirm with certainty that protoplasm does r in this respect, subtle as those differences may be. The oplasm of the plant is not identical with that of the nal, nor that of the nerve cell with that of the muscle , and it may well be that some differences are required in nature of the pabulum necessary for its restitution, or in case that the intimate character of the requisite hetic changes is of a variable range. The nutritive ls, that is to say, of all living matter are not exactly the e.

---

[1] General Physiology by Max Verworn, translated by Dr. F. S. Lee, 1899, p. 87.

will be desirable to consider these several varieties of stances a little more in detail, and first the *Proteids.* se bodies, which are met with in both animal and etable, tissues, conveniently fall into two groups which be termed (*a*) the free proteids and (*b*) the combined eids. The former includes the albumins and globulins, gulated albumins and the results of the proteolysis of e bodies—viz., albumoses and peptones. They differ, doubt, in their actual chemical composition but are narily distinguished from each other by differences in r solubility in water or in saline solutions, in the temperaat which they coagulate, &c. The combined proteids compounds of the simple or free proteids with other ies, from which they may often be separated by strong ls. The chief substances of this class are hæmoglobin, ch is an albuminous compound with a complex irontaining body; glyco-proteids, which are compounds of teids with carbohydrates; and nucleo-proteids or comnds of proteids and nucleic acid, which latter is an organic pound of phosphoric acid. It is evident that the comed proteids are more complex in their constitution than the pler proteids; they contain more atoms with consequent ease in size of the molecule and some of them contain ther element than the carbon, oxygen, hydrogen, ogen, and sulphur, of which all proteids are formed, h as iron or phosphorus. Intimately associated with all teids are various inorganic salts which form the ash when se substances are incinerated. Though by no means to regarded as living matter, it is likely that the combined teids are more closely connected with the bioplasm than the simpler bodies and it is certain that the nucleoteids are specially concentrated in the nuclei of the cells ich are probably the most important portion of the living t, whilst the bulk of the cytoplasm is made up of the pler proteids, chiefly globulins.

Nothing definite is known concerning the actual constitu of the proteid molecule as it may be represented by a onal formula—even the empirical formula is for the most t very uncertain. Some attempts at synthesis have been de but as yet with only partial success and such views provisionally obtain as to the intimate nature of the lecular constitution are derived from a consideration of products of their decomposition. From many of the teids, though by no means from all, by suitable treatment arbohydrate may be split off, which, wherever its exact ure has been determined, has proved to be a compound of ar with ammonia, leaving a moiety which contains the k of the nitrogen. This is the basis on which has been nded what is known as the glucoside theory of proteid stitution which is clearly applicable to only some of the teid bodies.

By another method of treatment—viz., by hydration, as effected by heat and mineral acids, or in a measure by the digestive ferments of the alimentary canal—the proteids are split up into amido-fatty acids, such as leucine, tyrosine, &c., and basic bodies, such as lysine and arginine, from the latter of which urea can be obtained. The combinations of these amido-acids, synthesised by Emil Fischer and named by him "polypeptids," throw more light on the constitution of the greater part of the proteid molecule than any other suggestion hitherto put forward. Among the most constant decomposition products of proteids to be found in the tissues and commonly referred to as nitrogenous extractives are urea, purin or alloxuric bodies, such as xanthine, hypoxanthine and uric acid, creatine, and creatinine. Others are met with in but very small quantities.

Of the living matter, at least in the highest forms of life, we have most knowledge of the composition of muscle and nerve, and it is impossible to avoid in reference to this subject mentioning the name of our distinguished Fellow, Professor W. D. Halliburton, whose work in this direction is of the highest order and forms the basis of our information.

The close similarity in behaviour of the juice that may be expressed from fresh muscle—muscle plasma—to that exhibited by blood plasma is generally recognised. In both cases under favourable circumstances coagulation takes place due to the formation of myosin and fibrin respectively, the precursors of
as myosinogen and fibri
in each case to be a ferm
fluid from its meshes—muscle serum and blood serum. After death the muscle plasma normally clots to a greater or less extent and causes the stiffening termed rigor mortis and it may be further observed that the muscle in its coagulation becomes acid, from the formation of sarcolactic acid, in place of the alkaline reaction that it exhibits when alive. Cold and the addition of neutral salts in both cases delays coagulation for the due occurrence of which in blood the presence of calcium chloride is essential, as there is some reason to believe is also the case with muscle. Further examination of the myosinogen, which practically forms (with the exception of a small quantity of nucleoproteid probably derived from the sarcolemma and from the nuclei of plain muscle plasma in which it is most abundant) the whole of the voluntary muscle fibre, shows that in its natural state it consists of two proteid bodies which coagulate at different temperatures and are precipitated by different amounts of neutral salines; for the more abundant of the two the name myosinogen is retained and the other, which is certainly a globulin "analogous to the cell globulin which is found in saline extracts of all protoplasmic structures," is termed paramyosinogen. Although it may be convenient to speak of these two proteids separately, they are not really independent. "The unit is protoplasm, and if one of its essential constituents is destroyed protoplasm as such ceases to exist."[2]

The ferments of muscle are also to be included among the proteid constituents of the tissue and most probably are of the nature of nucleo-proteids. One of these is a myosin ferment by which the muscle is coagulated; another is of proteolytic character and is "probably concerned in the disappearance of rigor mortis"; a third is amylolytic and converts starch into sugar—dextrose; a fourth which is glycolytic or sugar destroying and most likely is active in carbohydrate catabolism being made able to do so by the addition of the internal secretion of the pancreas.

The proteids of the nervous tissues form a considerable percentage of the solids, varying, according to Professor Halliburton, from 29 in the nerves to 51 in the grey matter of the brain. The most important of these bodies is a nucleo-proteid which contains but a low proportion of phosphorus and constitutes the greater part of the chromatin. In nerve cells this substance is not so restricted to the nucleus as it is in the cells of other tissues, for being distributed throughout the cytoplasm also it forms what are known as Nissl's granules. The other constituent proteids are both globulins. It is nucleo-proteids also that are the most abundant of the organic constituents of secreting glands, a circumstance that would appear to be connected with the specific functions of those organs—namely, the formation of ferments.

The next group of proximate principles of the tissues are the *fats.* The most abundant of these are the neutral fats consisting of the trivalent alcohol glycine $C_3H_5(OH)_3$ combined with fatty acids, palmitic, stearic, oleic, and others, water being lost in the combination and thus forming what are known as compound ethers or esters. By hydrolysis the fats are split up with the addition of water into the glycerine and fatty acids. The chief glycerides are tri-palmitin, tri-stearine, and tri-olein. Their solubility in ether and insolubility in water are among their most characteristic properties.

Constantly associated with protoplasm, of which they are decomposition products, are some extremely complex bodies which are included among fats, though differing considerably in composition and properties from those just mentioned. They are certainly most abundant in the nervous tissues and it is possible that their presence in muscle is due to the involved nervous elements; some are also to be found in the blood corpuscles, yelk of eggs, semen, bile, and milk. Probably the most important are the so-called phosphorised fats of which lecithin is the best illustration. This substance, of which really there are several forms, contains not only phosphorus in addition to carbon, hydrogen, and oxygen but also nitrogen. On decomposition with hydration it forms a fatty acid, glycerophosphoric acid, and cholin; the last named, containing all the nitrogen of the molecule, is an alkaloid allied to neurin and, as shown by Dr. F. W. Mott and Professor protoplasmic decomposition is cholesterin also found very abundantly in nervous tissue It is a monatomic alcohol composed of carbon hydrogen and oxygen

---

[2] *Biochemistry of Nerve and Muscle, by Professor Halliburton,* F.R.S., 1904.

Fat is most widely distributed throughout the tissues recent methods of staining having demonstrated its existence in cells not previously known to contain it Except in the cells of adipose tissue it is not to be found in the nucleus but it occurs as granules and droplets of various size in the cytoplasm, which it sometimes almost entirely replaces Besides this fat which is visible, by methods of extraction by ether or other agents, a further amount may be obtained from the tissues which otherwise give no indication of its existence but which clearly has to be taken into account in considering the relationship of fat to the living matter [3]

The *carbohydrates* of the cell closely correspond to the fats both in their distribution, not being met with in the nucleus, and in their relation to the proteid constituents, of which they may be in part decomposition products and in part material about to be dealt with by the bioplasm Like the fats also these substances are composed of the three elements carbon, hydrogen, and oxygen, the two latter in the proportion to form water With one exception the number of carbon atoms is six or some multiple of that number and hence they are known as hexoses They may be conveniently divided into three groups the monosaccharides ($C_6H_{12}O_6$), represented by glucose, galactose, and mannose, the disaccharides ($C_{12}H_{22}O_{11}$), cane sugar, milk sugar and maltose, and the polysaccharides ($(C_6H_{10}O_5)_n$ glycogen starch, dextrine, and cellulose The relationship between these groups is one of progressive condensation with the loss of a molecule of water and conversely, of course, by hydrolysis the higher may be changed to the lower forms Of these various

are the most

important, so

mal organism

he others that

obtain entrance to the body are converted, or tend to be converted, and it is in that form that the labile carbohydrate occurs in the body, whilst it is as glycogen or animal starch that they are stored pending metabolism in the liver, the muscles, and the tissues generally

In the muscles also there are to be found dextrine and maltose which are intermediate bodies in the conversion of glycogen into dextrose (Halliburton) There is another body, inosite, to be found in muscle which is of the same empirical composition as glucose, but is not really a sugar, being a member of the aromatic series Galactose can be obtained from cerebrins which are nitrogenous constituents of nervous tissue and to be regarded as glucosides, otherwise carbohydrates are not found as such in these tissues The

assium,

and ammonium, the carbonates of the same as well as of magnesium and calcium, together with sulphates and phosphates Among the less frequent elements found is iron and in very exceptional cells free mineral acids, hydrochloric and sulphuric, are met with In muscle the potash predominates among the bases and phosphoric among the acids and the same obtains in nervous tissues Sodium chloride is the most abundant salt in the blood Some work has been done by a committee of the British Association for the Advancement of Science (which has been appointed to investigate the micro chemistry of the cell) on the distribution of these substances in the cell From the experiments it would seem that potassium is not found in the nucleus and is much less abundant in the animal than in the vegetable protoplasm of unicellular organisms the former apparently being more resistant to its entrance from the surrounding medium than is the latter, but in the intestinal and excretory epithelia of vertebrates considerable quantities of potassium salts are to be found as excretory products The other important elements which enter into the composition of the protoplasm are phosphorus and iron, both of which are to be found in the chromatin of the nucleus, the latter in a "masked" form and probably combined with the carbon of the nucleo proteid Indeed, it may be said that there is good reason to suppose a most intimate and essential association of the various salts with the proteids in the living protoplasm, an association that is broken up when this material dies Oxygen and carbonic acid in a free state are to be found in all living matter, the latter as a decomposition product and the former concerned, as will be seen, not only in the decomposition processes, but also as playing a very considerable part in the consequent restitution

Such, then is an account, most imperfect it must be admitted, of the nature and composition of bioplasm The problem of nutrition is to explain how this composition is maintained, what preparation the ingesta as they are ordinarily presented to us undergo before they actually reach the cell, and, finally the removal of those waste products which result from the interchanges in the living matter attendant on the liberation of its specific energies

THE INGESTA.

In considering what are the essential characters of the ingesta, of the nutrient material, that is, which is needful to maintain the living being in structural integrity and functional capability, it has been usual to draw a distinction between animals and plants and it would appear that this distinction has frequently been made too absolute For although there can be no doubt as to the very different character of the food material required by, say, an oak tree and a man and how both would starve were the nutriment of the one supplied to the other, yet lower down in the scale no hard and fast line can be drawn Moreover, though the difference between the food of the higher animals and plants appears at first sight to be very considerable the distinction affects the nature of the materials as taken from outside, rather than in the form in which the actual nutriment is presented to the living matter For the maintenance in structural integrity and functional activity of the bioplasm, be it of a plant or an animal, the food supplied to it must be of a more complex character than such as is absorbed by plants Proteids and carbohydrates, fats, and some salts are equally necessary to animal and to vegetable protoplasm which correspond therefore closely in essentials In plants there is for the most part a greater extent of preparation of the ingesta before they are finally made use of, the range of synthetic capacity of the plant is so far greater, and animals start with their food where plants left off, the ultimate form of material presented to the bioplasm being similar in both cases

Experience has shown that the nutritive requirements of the animal organism are such that the food should contain certain proportions of different substances which correspond to the materials of which we have seen the living matter is composed A satisfactory diet should therefore consist of proteids, fat, carbohydrates, salts, water, and oxygen, and although the fats and carbohydrates may in great measure be made to replace each other, or may even be entirely withdrawn from the dietary, such modifications can only be tolerated for a limited period and are prejudicial sooner or later to the animal economy Each group of food stuffs is necessary, though perhaps in a somewhat different degree The proteid food is, however, a prime necessity, although, as will presently appear, it may undergo considerable retrogression in chemical complexity before it is presented for assimilation by the living matter This fact of proteid requirement implies that the animal organism is unable to synthesise from simple nitrogenous substances, such as ammonia or the nitrates obtained from outside and ingested as such, the complex proteid molecule which is the chief component of the protoplasm Proteid food stuffs then, are an essential requisite, whether they be of animal or of vegetable origin Not so with plants, however, which for the most part, and especially those which contain chlorophyll, are enabled to construct their proteid constituents from such simple nitrogenous compounds as the nitrates, particularly the ammonium salts There are even some forms which can assimilate free nitrogen, such as certain bacteria found in the soil and even some leguminous plants which are characterised by remarkable nodules on the roots formed as the result of invasion by these soil bacteria In these cases the range of synthetic power is at its maximum, the organism feeding on the chemical element itself and ultimately building up the complex proteid. In contrast to these stand some saprophytic and parasitic fungi which are absolutely dependent for their proteid construction upon some form of proteid, peptone or other, supplied as such, approximating in this respect to the animal requirements.

---

[3] By such methods Mr J B Leathes has shown that the different types of muscle vary in the percentage of fat they contain being greatest in the red muscles

Whilst there are many animals—the carnivora—which can exist upon an almost pure proteid diet such a plan could not satisfactorily be followed for an unlimited period in the case of man. In such a case, in order to obtain the requisite amount of carbon and hydrogen, such an enormous quantity of meat or other proteid food would have to be taken as to be almost prohibitive, owing partly to the difficulty of its digestion and partly to the ill effects such a food would entail in various directions. Hence a pure meat dietary within the limits that the individual can deal with falls short in the requirements as regards the carbon and hydrogen which consequently are supplied by the tissues of the individual which is rich in these substances—viz., the fat—and this in great part, though not entirely, explains the action of such a regimen as a treatment for obesity. In consequence carbohydrate and fat foods—one or both and preferably both—come to be a practical necessity. As diminishing the demand for proteid food beyond such an amount as is required to maintain nitrogenous equilibrium they are sometimes spoken of as "proteid sparers," the carbohydrates being of much greater value in this respect, a function that is also performed and more effectively by gelatin, since, though an albuminoid body and so allied to the proteids, it cannot entirely replace them as an article of diet, being apparently unable to supply the nitrogenous requirements of the protoplasm, or, in other words, cannot be built up into tissue.

Now the human organism, and with but few exceptions the animal organism generally, is unable to synthesise from simpler compounds, still less from the elements themselves, the required carbohydrates and fats which they obtain from the vegetable world. In plants these substances are abundantly formed and, indeed, the larger proportion of the constructive material of these beings is of carbohydrate nature—such as sugars, starch, and cellulose. Green plants have the power of so using the energy supplied by rays of light in the presence of chlorophyll as to synthesise carbon dioxide and water into these more complex bodies; the nitrate and nitrite bacteria employ the chemical energy derived from the oxidation of ammonia to nitrous or to nitric acid for the same purpose and it is "possible that organisms may be discovered which are able to make use of other forms of radiant energy for the assimilation of carbon from carbon dioxide."[4]

This dependence of animal and plant life—indeed, this in great measure mutual dependence, since the waste products of the former constitute the food of the latter—is one of the most striking of the harmonies of nature. That master of word-painting, Ruskin, thus expressed it: "The earth in its depths must ever remain dead and cold, incapable except of slow crystalline change, but at its surface which human beings look upon and deal with, it ministers to them through a veil of strange intermediate being; which breathes but has no voice; moves but cannot leave its accustomed place, passes through life without consciousness, to Death without bitterness; wears the beauty of youth without its passion, and declines to old age without its regret."

Although living beings are continuously liberating energy with ceaseless change in the condition of their component materials it does not follow that the intake of pabulum is equally continuous, rather is it periodic. It follows, therefore, that animals and plants must contain a reserve of material suitable for use in tissue construction and force production and so disposed that it may be conveniently drawn upon. In considering the food, therefore, account has to be taken not only of that which is taken into the body from time to time but that which is already stored up in the body in reserve and it is a question whether in some circumstances all the intake may not be stored up for a time before being actually presented to the living matter for disposal—passing as it were through a resting stage. In vegetables this reserve material forms no inconsiderable part of the entire plant. In them the opportunities for the absorption of food are likely to occur at most irregular intervals, sometimes of long duration, dependent as they are upon the amount of light, heat, and moisture. The duration and character of the seasons, the climate, and many other disturbing circumstances, apart from their inability to move from place to place in search of food, render the necessity for a reserve proportionately greater in them than in animals. In plants the reserve food consists chiefly of starch which tends to be accumulated in special reservoirs such as the roots and tubers, but also in the stems and leaves; oils also are stored up and proteids in the form of what is known as aleurone in the seeds, particularly of the leguminous species. Fat in adipose tissue and elsewhere, glycogen, and the proteids of the tissues form the reserve in animals, the first two being probably those which are most properly to be regarded as reserve, since the supply of the needful amount of proteid is commonly forthcoming at sufficiently frequent intervals to meet the demand, but when there is deprivation of food the proteid constituents of the less important organs furnish what is wanted by those structures upon which life depends and to that extent may be looked upon as a potential reserve. It is worthy of note that in plants, and in a great measure also in animals, this reserve which is prepared from the ingesta and represents what is over and above the immediate nutritive needs of the individual is not actually in the form in which it is offered for assimilation; the starch or glycogen has to be converted into sugar before it can be utilised, it has, that is to say, to undergo a change similar to that effected by digestion in the alimentary canal of an animal. This fact has given rise to the comparison of "a plant when living on its reserve materials to an herbivorous animal both as regards the substance of its food and its manner of making it available for nutrition" (Reynolds Green).

Of the inorganic salts sodium chloride is the only one that is purposely added to our food either in the course of its preparation or when being consumed. The other members of this group of substances as previously enumerated which are found in association with the protoplasmic molecule are amply supplied in the ordinary articles of diet; the phosphorus required is derived not from the mineral phosphates but more probably from some organic compound of the element, and it is this circumstance that affords such justification as may be for the employment of glycerophosphates in many cases of impaired nutrition. As bearing on the probable share taken by these substances in the body nutrition it may be mentioned that the proportion of them in the milk of various animals appears to vary directly with the rate of growth of the suckling, thus, e.g., cow's milk is much richer than human in salts and the calf grows much more rapidly than the infant. Further, the food of herbivorous animals contains a much larger proportion of potash than that of the carnivora and the need for extra quantities of chloride of sodium for the former animals is well known. An important purpose subserved by some of these inorganic bodies is the maintenance of the alkalinity of the fluids which bathe the protoplasm, that reaction being a necessity for the exhibition of living activity.

Regarding the quantity of aliment that is necessary to maintain a state of metabolic equilibrium and a condition of general well-being some observations of precision have lately gone a considerable way to confirm what has for long been supposed to be the case—viz., that much more food is ordinarily taken than is absolutely required. The method of estimating the energy-value of food by ascertaining the number of calories that a given weight of it yields on combustion has enabled us to formulate a dietary with greater approach to the needs of the organism and to economy than has hitherto been the case. In a paper read in April last year before the National Academy of Sciences at Washington Professor Chittenden showed as the result of a careful and prolonged series of observations made at the Sheffield Scientific School of Yale on a number of the professors, of the students, and of United States soldiers who were placed at his disposal by the Government that the quantity of the solid ingesta required was but a third to a half of that usually taken by the average man. The amount of meat was gradually reduced but enough bulk of food in all cases was consumed to satisfy the appetite. By a very thorough mastication and insalivation of the food—which was an important part of the experiments—it was found that this sense of satisfaction was attained with a smaller quantity than is usually taken. The general hygienic conditions of the subjects of experiments were carefully regulated, with the result that on the greatly diminished diet the individuals kept their weight and vigour and even increased their muscular power and endurance. Although, as I have said, the outcome of these experiments gave a scientific sanction to ideas that were very widely entertained, they are distinctly at variance with the most authoritative pronouncements of those who have hitherto written on the subject.

---

[4] Pfeffer: Physiology of Plants. Translated by Dr. Ewart. 1900. P. 292.

In one of the latest works on the subject of dietetics—viz., that by Dr. R. Hutchison—it is laid down that the requisite diet for a man of ordinary weight doing a moderate amount of muscular work should be of a value in potential energy of from 3000 to 3500 calories and that for such an individual "the daily consumption of proteids should never be allowed to sink below 100 grammes but should preferably be 125." This is fully twice as much as that allowed by Professor Chittenden. Whether the more thorough mastication and insalivation insisted on by the latter observer explain the adequacy of the much reduced amount of food remains to be proved, but certainly general experience so far has been against any such reduction in the intake. The time is not yet ripe to accept the dictum "that the animal functions, the tonicity of the structures and organs, in short the normal intra-systemic equilibrium, are the better maintained, the more the sum of the ingested assimilable nutrients is limited to the amount absolutely necessary to keep the body in metabolic balance."[5] The actual character of the food as it is presented makes a good deal of difference. If it be of a coarse nature, such as forms the bulk of that of the working population, a good deal of the energy obtained from the food is used up in the preparation of the rest of it, so that the total and the assimilable nutrients are not by any means the same. It is here perhaps that the advantage of thorough mastication is to be found, but at the same time the general tendency of the diet of the population is to improve in the digestible and assimilable character in which it is offered for consumption.

It will be obvious that the relative proportion in which the constructive and destructive phases of metabolism prevail, which especially governs the amount of food wanted, will in great measure be conditioned by the period of life. Until maturity is attained—i.e., during the period of growth—a large proportion of the intake is devoted to the building up of the tissues and as the demand for chemical energy and for heat is then at its greatest in order to effect the requisite syntheses, the need for fuel food is relatively at its greatest also, hence the total amount of food required per given body weight is far greater in the growing stage than it is later when full bulk is reached. During that time and previously to the decline of life the main purport of the ingesta is to supply the requisite energy and just enough only to maintain the mechanism. A lessened quantity is appropriate to old age when tissue construction has ceased and a diminished energy is manifested in all directions.

THE RELATION OF THE BIOPLASM TO THE INGESTA.

Such, then, are the two material factors of the nutrition problem—the living matter of unknown and perhaps unknowable exact composition, of the chemical nature of which we have any conception from its derivatives only; and, on the other hand, its food which corresponds in great measure to these same derived substances. It now behoves us to consider the active relation of these factors to one another, how it is that the bioplasm deals with the food and the outcome thereof. I need scarcely remark that very much of what one can say in reference to this question is quite hypothetical; but at the same time it may be observed that some ground for these hypotheses is furnished by the results of experiments and such hypotheses but serve to explain in our present state of knowledge the problems with which we have to deal, whilst it is perfectly admitted that such concepts are subject to modification or even overthrowal, should well ascertained facts render this necessary.

Foremost among these fundamental notions is that the living matter in mass, as also in its constituent molecules, "consists of a permanent part which is not concerned in the performance of function and of a collateral part which is used—i.e., disintegrated in every transition of the molecule from the inactive to the active state, to be immediately reconstituted when action ceases."[6] Such an assumption does not exclude the idea of the "permanent part" undergoing a certain amount of wear and tear which necessitates its repair or renewal. And it is further very certain that the "collateral part," the changes in which underlie the manifestations of energy which the living matter exhibits, is of a higher degree of chemical complexity than the ingesta which are destined to replace it and maintain the supply of fuel material which has undergone disintegration. There is, therefore, a series of synthetic changes which the ingesta undergo to enable them to become integral parts of the bioplastic molecule, as there is another series of changes associated with the breaking down of the molecule. Whilst [illegible]

We are often in the habit of speaking of a progressively ascending series of changes which the food undergoes in its passage towards assimilation by the existing living matter, becoming as it does living, and then passing downwards through another series of changes, forming in our minds somewhat the conception of a pyramid up the slopes of which the requisite food-stuffs travel with ever-increasing complexity of composition until when the summit is reached the molecule topples over, as it were from sheer instability, to pursue its descent towards those simpler atom groups which we recognise as waste products, liberating in its progress that energy which it had accumulated in the progress of its synthesis. Although I say we conceive of the anabolic processes as succeeded by those of katabolism it is more than probable that they are in great part coincident and even mutually involved. It may even be the case also that the stimulus to restitution is to be found in the preceding disintegration, the former taking place at the moment that the living molecule splits up.

It has also to be remembered that for the carrying out of the synthetic changes energy is requisite—kinetic energy, that is, which becomes potential in the advancing molecule, later to be reconverted into kinetic as the molecule undergoes decomposition. It is generally believed that the requisite energy for this purpose is derived, in the higher animals at least, from the heat and chemical energy liberated in the course of katabolism—that is to say, the very constructive changes are dependent for their production upon coincident decompositions—and one cannot but marvel at the character and nature of this energy which effects both the synthetic and analytic changes if we compare it with what is requisite to effect those same integrations and disintegrations in the comparatively few cases which we have been as yet able to imitate in our laboratories. The following illustrations will suffice. Indol is a product of proteid decomposition which is readily formed by certain bacteria in the intestine; to produce the same result in our test tubes it is necessary to fuse the proteids with caustic alkalies—a proceeding that would be absolutely destructive, of course, of the living tissues. By passing an alternating current through a solution of ammonium carbonate or by the action of heat on ammonium carbamate urea may be formed and the same occurs on boiling proteids for some hours with hydrochloric acid. Now these processes, which require very strong reagents and some considerable time, are rapidly and easily effected by the living cells or their products.

It is the dependence of the synthetic processes upon the energy supplied by katabolism that justifies my saying, as I did just now, that both anabolism and katabolism are in a great degree coincident and in a measure mutually involved. So far as we know it is by chemical energy that synthesis is effected in the animal body, just as "muscular work is accomplished by the transformation of a corresponding amount of chemical energy,"[7] but green plants have the power of effecting the required combinations by means of sunlight and a few members of the vegetable kingdom can utilise the heat rays of the sun for the same purpose; in both these cases the presence of a pigment, chlorophyll or other, is essential Whether the hæmoglobin of the blood can play a similar part in animals or whether electrical energy or any other forms of radiant energy are equally capable I do not know.

But whilst we realise that a complex series of anabolic changes intervene between the nutriment as taken into the body and its final incorporation into the protoplasmic molecule, changes which are closely related to those of a katabolic character which result in the production of the body waste, there still remains to be explained the essential point of the whole problem which I have just spoken of as the incorporation into the molecule of the pabulum. The most plausible hypothesis that has been put forward to give an exact meaning to this process which we denominate to a right angle as he lies in bed and then extend the knee. 5. Lumbar puncture is an important aid to diagnosis. The object of this operation is to withdraw for examination some of the cerebro-spinal fluid from the lower part of the spinal canal. The patient is put in such a position as makes the lumbar spines prominent and a long fine trocar and cannula are introduced in one of the lumbar interspaces, usually the third, because the level of this space is easily found, being on a line drawn between the highest points of the crests of the ilium. Some operators introduce the trocar in the middle line, others at a point slightly to one side of it, with an inclination towards the middle line. The operation is easy in children but in adults rather more difficult owing to the depth at which the tube of dura mater lies. The fluid thus obtained is in the normal subject clear but in most cases of meningitis it is turbid or even purulent. The sediment obtained from it after standing or by centrifugalisation can be examined microscopically or by cultural methods and it may be possible in some cases to tell by these means not only that there is meningitis but to what micro-organism the meningitis is due. But a negative find does not disprove the existence of disease and it is said that in tuberculous meningitis there is often very little sediment and that no tubercle bacilli are to be found. I will now consider the cases which form the subject of this lecture.

---

[6] Professor Sir J. Burdon Sanderson, British Association for the Advancement of Science meeting, 1904.

[7] Burdon Sanderson: loc. cit.

CASE 1.—A young man, aged 20 years, was admitted to the casualty ward on Nov. 28th, 1904, in a semi-conscious condition. A meagre history was obtained from his companion to the effect that for some little time he had not looked well and that six days before admission he went to bed with pain in the lumbar region and in "the ribs"; next day he coughed, and the day after that —i.e., four days before admission—he vomited twice and was feverish. Three days before admission he had headache which soon became worse. Two days before admission he became delirious and noisy, "yelling" for an hour together, and he refused food. It was supposed that he had had hæmoptysis during his boyhood. On admission he was quiet when left alone but would answer no questions nor would he tell his name, only saying, "Let me alone," resisting when examined and wrinkling up his nose and upper lip when disturbed. Thus examination was very difficult, but it was made out that his temperature, pulse, and respiration were natural, that there were no abnormal physical signs in his chest, and that he had no optic neuritis. It might have been thought, therefore, that he was either insane or hysterical, but two symptoms of importance told against this—viz.: (1) that his head was held rigidly and it appeared to give him pain when attempts were made to bend it forward; and (2) that his knee-jerks were almost absent. These two points, coupled with his state of cerebral irritation, suggested a meningitis. The next day (Nov. 29th) he was quieter, but as no urine had been passed a catheter had to be used; this upset him again. He refused his food and had to be fed nasally, which was the occasion for more violence. The bowels, which had not acted during the week's illness, were now relieved by calomel. There was a slight rise of temperature (99° to 100° F.), a further indication that his illness was not due to mere nervousness. Things continued thus till Dec. 1st (three days after admission), when he seemed distinctly quieter and better, though his temperature had risen further (102°) and this apparent improvement was maintained till the 6th. He could be examined more thoroughly now; Kernig's sign was found to be present; the knee-jerks were still absent. A blood count gave 19,000 leucocytes; the Widal test was negative. There was pain in the left hypochondrium but the spleen could not be felt. Though conscious and though not paralysed in his limbs he began to pass his excreta beneath him. There were still no signs of disease in the lungs (Dec. 4th). On the 7th he suddenly became comatose, his breathing being stertorous and his colour bad. Although he came round in half an hour his general condition soon after this began to get much worse; his temperature rose (with fluctuations), reaching on the 8th a maximum of 102·5°. His pulse became frequent and feeble, his respirations rapid, and his colour bad. He died at midday on the 10th, having been ill for 19 days. No lumbar puncture was made on account of his restless, irritable condition, in which he resisted all manipulation. Meningitis was diagnosed but we did not expect that it would prove to be a tuberculous meningitis.

Necropsy.—At the post-mortem examination an irregular cavity with a calcareous wall was found at the extreme apex of the right lung and a focus of caseation with some adjacent pleural adhesions at the upper part of the right lower lobe. Neither of them had been detected during life. The rest of the lungs was simply stuffed with discrete, firm, miliary tubercles. As the patient had neither sign nor symptom of lung disease at first, it seems probable that this outbreak of tubercle took place during the last few days of his life. The spleen was also crammed with miliary tubercles and there were very many on the surface of the liver. All the other organs were natural excepting the meninges. The condition of these was as follows. In the arachnoid and pia mater at the base of the brain was a turbid gelatinous exudation distending the membranes and gumming together the Sylvian convolutions. These parts, the chiasma, the perforate spaces, and the under-aspect of the cerebellum were the principal seats of the effusion, but there was some on the upper surface of the cerebellum. There was an increase of fluid in the ventricles. (No miliary tubercles could be plainly seen and the lymph looked rather more opaque than is usual in tuberculous meningitis, but taking the condition of the other organs into consideration we can hardly doubt that the meningitis was tuberculous.) The spinal cord was covered by a similar effusion, fading away gradually towards the filum terminale.

The following remarks may be made on this case. 1. The meningitis, as is the rule in tuberculous meningitis, was associated with a general tuberculosis. But to judge from the symptoms the tuberculosis of the meninges distinctly preceded the acute outbreak in the lungs. 2. The acuteness of the onset and the severity of the mental symptoms (the patient was practically maniacal) did not resemble the ordinary form of tuberculous meningitis in children, when the development of the disease is much more gradual. But you will find, I think, that tuberculous meningitis in the adult very often presents unusual features of this kind. 3. The spinal meninges were as deeply involved as the cerebral. There are, I know, rare cases of tuberculous meningitis in which the spinal lesion predominates, but usually the cerebral lesion is most marked. In this case the brain and the cord were equally affected. The spinal meningitis could be diagnosed during life by the presence of Kernig's sign, the absence of the knee-jerks, and possibly by the condition of the sphincters.

CASE 2.—The second case was that of a servant girl, unmarried, aged 22 years, who was admitted to Elizabeth ward on June 21st, 1904, her chief complaints being retraction of the head and loss of power in the legs. Her personal and family history was unimportant. The history of her disease was as follows. Three weeks ago she had pain in the back, thought to be rheumatism; for this she left her place and went home. Ten days ago she vomited, once only; the same day her head was noticed to be retracted. Three days ago her knees gave way so that she could not walk. Her memory began to fail at the same time. I find no mention of headache but if I remember right she had headache after admission. She was said to have had otorrhœa and earache but nothing wrong was discovered with her ears after admission, so that possibly this may be discounted. On admission she looked flushed and anxious, her temperature was but slightly raised (99° to 100° F.), but her pulse was very frequent (144 per minute). There was marked retraction of the head and the back was rigid and showed a certain degree of opisthotonos. Her mental condition was peculiar; she was not delirious or violent but she talked in a childish excitable way and appeared to have frequent lapses of memory. There was severe insomnia. Dr. H. M. Fletcher, who saw her on the first day for me, noticed a distinct weakness of the left facial muscles (in both the upper and lower parts of the face). Though this passed off very quickly it is important as showing that the disease probably affected at the outset the base of the brain as well as the cord. The upper limbs were not affected at first. The chest was natural, there was some tenderness in the abdomen, especially in the region of the spleen, but nothing abnormal could be felt there. The lower limbs were tender to touch; there was flaccid paralysis of both, complete in the left and almost complete in the right. There was a certain amount of anæsthesia or rather blunting of sensation in the legs, but not sufficiently definite to be set forth in a chart. The knee-jerks were absent; no plantar reflexes could be obtained. Kernig's sign was obtained in both lower limbs. The bladder was distended and 33 ounces of urine were drawn off. In the sacral region there was a small shallow sinus, the nature of which was not quite obvious, but a probe entered only a very short way. It certainly did not penetrate to the spine and we finally came to the conclusion that it had nothing to do with her disease. The tenderness of the lower limbs, the flaccid paraplegia, with absence of the knee-jerks, coupled with the peculiar mental state, suggested a peripheral neuritis, but this would hardly account for the paralysis of the bladder, still less for the retraction of the head and rigid spine. A diagnosis of meningitis seemed best to cover the facts. A lumbar puncture was made on two occasions but no fluid was obtained. Probably the interior of the meninges was not reached, seeing that post mortem an abundance of pus was found there. The course of the case was as follows. The retraction of the head improved so that by the end of June it had almost disappeared. The sleeplessness, very troublesome at first, yielded slowly to regular doses of bromides. She remained odd mentally, though she improved slowly in this respect. In the course of the first three weeks the paralysis spread to the hands. She complained of "pins and needles" in them and loss of power so that she could not feed herself. The bladder did not recover, but instead of dribbling from over-distension, as on admission, there was reflex incontinence—i.e., the urine passed involuntarily at intervals. In spite of all care some cystitis developed. The patient became very wasted, as generally happens in prolonged cases of meningitis. Nevertheless, after about six weeks' time she appeared to be improving slightly and I began to think she might eventually recover when events took place for which we were not prepared and which brought about her death. On August 10th there was a discharge of greenish pus per rectum, about eight ounces in amount. A rectal examination made a few days later disclosed a boggy patch on the posterior aspect of the gut. The pus continued to discharge. Early on the 21st she complained of abdominal pain; the abdomen was found to be more distended than usual, resistant, tender, and dull in the flanks. The pulse, never good, became steadily more frequent and feeble and she died that morning.

Necropsy.—The post-mortem examination (made by Dr. Horton Smith Hartley) explained the manner of her death. The brain and its membranes were natural, save that over the cerebellum and the medulla the pia mater was possibly more opaque than usual. The spinal cord showed a purulent meningitis most marked in the lower part of the cord but extending in a less degree up to the cervical region. The tube of the dura mater was full of pus. This pus had made its way along the nerve roots and set up irregular abscesses behind the spinal column in the muscles of the lower dorsal and lumbar regions, on either side of the spinal column anteriorly, and also a large abscess behind the rectum. This last-mentioned abscess had burst into the rectum a little way above the anus, [illegible] producing the [illegible] the general [illegible] the pelvis, thereby setting up a peritonitis from which the patient died. There was pus in the bladder and in the pelvis of the kidneys and the mucous membrane of both these parts was injected. The bones of the spinal column, the sacrum, and the sacro-iliac joints were carefully examined but no source of infection could be found such as might have produced a meningitis. The conclusion arrived at, therefore, was that there was a primary spinal meningitis with secondary abscesses, one of which had perforated the peritoneum and so caused death. The pus from within the meninges of the cord yielded a pure culture of staphylococcus pyogenes albus.

A CASE OF EXCISION OF THE RECTUM FOR CARCINOMA RECTI.

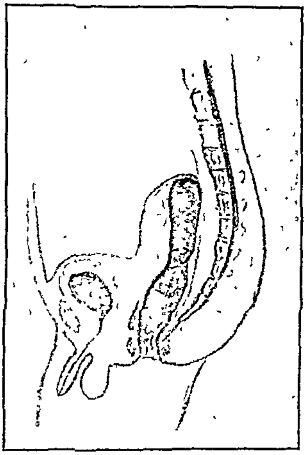
BY F. C. WALLIS, M.B., B.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO CHARING CROSS HOSPITAL, ETC.

THE following case is so satisfactory in the ultimate result obtained that it seems worth while to record it, having regard to the fact that the practical results in these operations are often so disheartening.

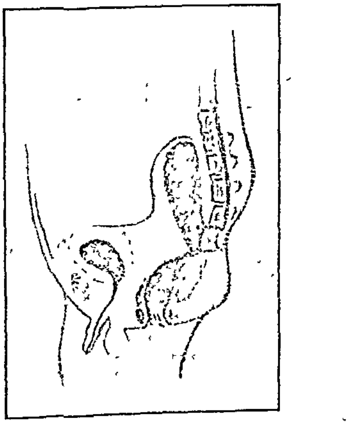
A man, aged 72 years, was admitted to St. Mark's Hospital on Jan. 25th, 1904, suffering from carcinoma recti. The patient had always enjoyed good health until eight months previously to admission when he noticed a "stoppage of water" which was followed by diarrhœa. The diarrhœa had persisted ever since and was accompanied by loss of blood. There was no offensive discharge or any great pain. He had lost 21 pounds in weight during the last three months. He had always been a strong healthy man. Rectal examination revealed an ulcerated growth, mainly in the posterior wall but extending also on to the anterior wall, commencing about three and a half inches from the anus. The growth appeared to be fixed to the deeper tissues. It was decided to prepare the patient for operation and to examine him again under an anæsthetic, being prepared to remove the growth if it was thought possible to do so.

FIG. 1.



Sagittal section of pelvis showing diagrammatically the condition before the first operation. Growth seen in rectum.

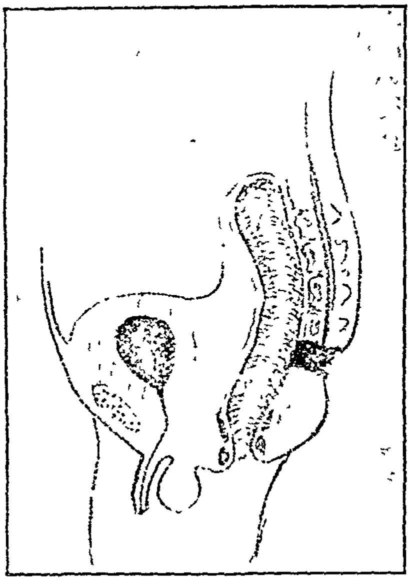
FIG. 2.



Showing condition after the first operation. Sacral anus formed. Growth removed.

Operation was performed on Jan. 28th. The patient was anæsthetised and the rectum was examined. It was then found that the growth was freely moveable and that the upper limit could be felt. A skin incision was made from the fourth sacral spine to the tip of the coccyx and all structures were divided down to the bone. The coccyx was removed but the sphincters were left untouched and a portion of the sacrum was taken away by bone forceps. The rectum was freed above and below the growth, the peritoneum being freely opened. A stout silk ligature was passed round the bowel above the growth and the rectum was divided and turned down and again divided below the growth, about three inches of bowel being removed. The two ends could not be united, but one or two sutures approximated the cut surfaces anteriorly and then the upper end was sutured to the sacral opening. The remainder of the incision was closed with silkworm-gut sutures after the wound had been thoroughly irrigated with hot hazeline solution and packed with iodoform gauze. A large tube was passed into the bowel and packed round with iodoform gauze. The operation was remarkably free from hæmorrhage, the bleeding being largely controlled by swabs saturated with hot hazeline solution. The patient made a good recovery and left the hospital three weeks later with a sacral opening.

FIG. 3.



Showing present condition. Sacral anus closed. Upper part of rectum brought down to anal margin. Sphincters intact.

He was readmitted on May 9th, when an ineffective attempt was made to close the sacral opening by freeing the edges of the mucous membrane and suturing the mucous membrane posteriorly, approximating the skin edges and leaving a gauze drain in. This all broke down and he left the hospital in much the same condition as when admitted. He was admitted again on Oct. 10th as the want of control caused him great mental distress. Operation was performed on the 13th. The bowel was freed from its attachment round the sacral opening and separated upwards for about three inches, the peritoneum being again freely opened. The distal part of the mucous membrane between the anus and the sacral opening was entirely removed and the bowel was brought down to the anus and stitched to the skin. The patient made an excellent recovery with the exception that on the eighth day he had a bad rigor and a rise of temperature to 105·6° F. During the rigor the bowels acted freely. This was the first action since the operation. He has now to all intents and purposes a normal rectum with perfect sphincteric control and is in excellent health.

The following points are of practical interest: (1) The control of the hæmorrhage by means of hot hazeline solution of the strength of one drachm to the pint at a temperature of about 100°; (2) the wound was irrigated twice daily after the first 48 hours with either saline or boric solution (this I make a routine custom in all operations for rectal carcinoma); (3) as few stitches as possible were applied to the approximated edges in order that drainage might be as free as possible; (4) the greatest care was taken to divide the bowel well above the growth and when possible well below it and to avoid infecting the wound from the bowel (this was avoided by ligatures and guards); (5) the patient sat up in bed as soon as possible for better drainage from the wound; and (6) the fact that perfect control and practically normal sensation were obtained after such an operation is particularly interesting, having regard to the statements which are made as to the loss of sensation following excision of the lining membrane of the anus.

Harley-street, W.

ON THE ABSENCE OR MARKED DIMINUTION OF FREE HYDROCHLORIC ACID IN THE GASTRIC CONTENTS, IN MALIGNANT DISEASE OF ORGANS OTHER THAN THE STOMACH.[1]

BY BENJAMIN MOORE, M.A., D.SC.,
JOHNSTON PROFESSOR OF BIO-CHEMISTRY IN THE UNIVERSITY OF LIVERPOOL;

H. E. ROAF, M.B. TORONTO,
JOHNSTON COLONIAL FELLOW, UNIVERSITY OF LIVERPOOL.

IT is well known that free hydrochloric acid is absent in nearly all cases of cancer of the stomach. This was first noticed by Reinhard von den Velden[2] in 1879 and has been the subject of much observation and criticism since then but may now be taken as a well-established fact. For example, Osler[3] records that in 94 cases of cancer of the stomach in which the contents were examined free hydrochloric acid was absent in 84 cases. The absence of the free hydrochloric acid has till now chiefly been studied as a diagnostic sign in doubtful cases of cancer of the stomach and has scarcely been considered from any other standpoint. The presence of free hydrochloric acid in a small percentage of cases of cancer of the stomach, as well as the undoubted absence or diminution of the acid in other conditions of the organ or in general disease arising from other causes than cancer, take away greatly from the value of the absence of free hydrochloric acid as a diagnostic sign in doubtful cases suspected of being carcinoma ventriculi. While the above statement may be freely admitted the observed fact remains that in 90 per cent. or over of cases of cancer of the stomach there is no free hydrochloric acid or the acid is reduced to a minimal trace.

Looking away entirely from the question of diagnosis, this is one of the few established pieces of knowledge that we possess regarding cancer and the cause of the absence of the acid deserves careful inquiry on its own account, since knowledge of this may increase our information regarding the disease with which it is associated. Local conditions in the stomach itself have hitherto been made to furnish explanations of the absence of the acid in the gastric secretion in cases where a cancerous growth has invaded that organ. Such growths in many cases are situated in the pyloric region and in process of growth begin to constrict the exit from the stomach. The consequences are dilatation and retention of food in the stomach which causes continued irritation of the secreting mucous membrane and this in time alters the normal character of the secretion which in the end ceases to be acid and becomes simply a catarrhal secretion. Hence the absence of acid, as in long-continued irritation of the mucous membrane by any other means, is due to chronic gastritis giving rise to a catarrhal flow. That this view, which is the usual one with regard to the absence of the acid, does not exactly fit the known facts is seen from the observations of G. Honigmann and C. von Noorden[4] who examined series of cases of dilatation and retention of food in the stomach due, on the one hand, to cancer and, on the other, to different causes. In the cancer cases the acid was absent or reduced to traces while in the dilatations unaccompanied by cancer soon after ingestion of food free hydrochloric acid was present. Secondly, in many cases the absence of acid has been proven early in the development of the growth before there has been any dilatation or marked gastritis. An alternate hypothesis which has been advanced is that the acid is neutralised by alkali poured in from the ulcerating surface of the growth, but this view is also negatived by the early suppression of the acid which often occurs before the surface breaks down from ulceration.

---

[1] Abstract of a paper communicated to the Royal Society on Feb. 28th and read on March 16th, 1905.

[2] Deutsches Archiv fur Klinische Medicin, vol. xxiii., 1879, p. 31.

[3] Principles and Practice of Medicine, third edition, p. 491.

That a small cancerous patch in one region of the stomach occasionally so situated that it leads to no marked dilatation of the organ nor to any continued retention of food should, *by some local irritation*, cause the suppression of the acid secretion in the remaining apparently healthy portions of the mucosa, does not seem to present a very feasible explanation. But if the suppression be not due to local action to gastritis, or to the pathological condition of one portion of the mucosa affecting all the remaining portions what can the explanation be?

The idea presented itself that the suppression of the acid [illegible] lition in the body, to altera[illegible] some way, either by products [illegible] or as a result of changes in the blood which might lead both to the abnormal growth and atypical mitosis of the cancer cells and to such changes in the nutrient medium of the oxyntic cells that these could no longer separate hydrochloric acid from the inorganic constituents of the plasma. Such a view if it could be substantiated experimentally, would naturally give a new importance and a different aspect to what is already one of the most important experimental facts known about carcinoma. The testing of this view was the object set forth in the observations recorded below which have shown that *the absence of free hydrochloric acid in cancer of the stomach is not due to local action in that organ, for hydrochloric acid is absent or reduced greatly in amount whatever may be the situation in the body of the malignant growth.* It follows that the absence of the acid is due to some change in the blood which change may either be a common cause of the growth and the absence of the acid or may be the result of the growth and the cause of the absence of the acid. The significance of this fact will be reverted to after the results of the observations have been described.

The amount of free hydrochloric acid present in the stomach contents was determined in 17 cases of malignant disease situated in different situations such as the uterus mamma prostate, rectum tongue cheek and mouth and in about two thirds of the cases the free hydrochloric acid was found to be entirely absent while in the remaining cases the amount found was much below the normal being reduced to a mere trace in all except one case where it reached about one fifth of the average amount obtained in control determinations carried out upon ourselves.

METHODS OF EXAMINATION.

The test meal given in each case was that recommended by Ewald of a pint of tea without sugar or milk and a round of dry toast.[5] The length of time before withdrawal of the contents of the stomach was noted in each case and was usually about one hour. The contents before testing were filtered from undigested residues of the food and the tests in all cases were commenced as soon as possible afterwards.

The quantitative volumetric testing was performed by neutralising with deci normal caustic soda solution with the indicator mentioned in each case. For convenience of comparison the results are expressed in terms of the equivalent amounts of hydrochloric acid. But it must of course be understood that in the case of the phenol phthalein and di methyl amido azo benzol indicators the figures do not represent actual free hydrochloric acid but acidity expressed as the equivalent amount supposing it were all hydrochloric acid.

(*a*) *Total acidity.*—This was determined in the usual way by titration of ten cubic centimetres of the gastric contents with phenol phthalein as indicator. The amount so obtained gives the total acidity due to hydrochloric acid (when present) organic acids and acid salts (such as acid phosphates).

(*b*) *Acidity to "di methyl indicator.*—This indicator does not give as originally supposed by its introducer (Topfer[6]) the free hydrochloric acid alone but in addition any acidity due to free strong organic acids such as acetic lactic and butyric. Accordingly, this figure is usually higher than that for the free hydrochloric acid given by the other methods described below and the free hydrochloric acid may safely be taken as below the value of this reading. When the organic acids are low in value it gives an approximation to the free hydrochloric acid and as it is often used as a clinical method it is here given for purposes of comparison.

(*c*) *Acidity to Gunzburg's reagent*[7] (phloroglucin and vanillin).—We have found this reagent most trustworthy both as a qualitative and a quantitative test. We have convinced ourselves by experiment that the test unmistakably shows 1 part of free hydrochloric acid in 30 000 parts by volume and can be relied upon for accurate results in rapid clinical work where quantitative results are desired as they always should be.

The use of the Gunzburg reagent in conjunction with titration with deci normal alkali which was first recommended by Mintz[8] was carried out by us as follows. Ten cubic centimetres of the filtered gastric contents are taken two drops are removed with a glass rod to a porcelain capsule a drop of the reagent is added from a dropping bottle and the mixture is evaporated to dryness preferably on a steam or water bath. If even a trace of free hydrochloric acid is present the characteristic red colour appears. In that case a quantity of deci normal alkali is added to the ten cubic centimetres of filtered contents from one or two tenths of a cubic centimetre to one cubic centimetre according to the depth of colour obtained on the initial testing. The process of testing is then repeated, if a positive result is obtained *more alkali is added the testing repeated and so on until* a negative result is obtained. Near the end when the reaction is less marked the alkali is added in quantities of 0·1 cubic centimetre at a time. A little practice enables one to carry out the testing in about five minutes in all and reduces the number of operations to four or five. As only [illegible] removed for each test and the [illegible] removed [illegible] e cases of [illegible] he outset [illegible]

[illegible] *f free and combined hydrochloric acid.*—We have used this method as a grav[illegible] von Jaksch[10] The [illegible] present into bariu[illegible] te (previously tested and found free from soluble barium salts). Ten cubic centimetres of the gastric contents are taken and about half a gramme of the fine dry barium carbonate powder is added. The mixture is well shaken up and allowed to stand for about an hour, it is then evaporated down to dryness in a platinum or nickel crucible and incinerated. In the process of incineration the barium salts of the organic acids if any are present are destroyed and barium carbonate is re formed while the barium chloride formed from the hydrochloric acid (free or combined with proteid) present in the gastric contents is unchanged in the process of incineration. After incineration the incinerated mass is extracted several times with hot water and the washings are filtered free from barium carbonate. The end of the process consists in determining the amount of barium salts in solution which we have done by precipitating as barium sulphate collecting on a Gooch crucible and weighing. From the weight the amount of available hydrochloric acid uncom[illegible] is easi[illegible] stated [illegible] acid free or combined with proteid but [illegible] of inorganic acid (hydrochloric or other acid possessing a

[5] Except in one case (Case 9) where the toast could not be taken on account of the situation of the growth and the test meal was a pint of gruel and two pints of water administered by the stomach tube and withdrawn after one and a half hours.

[illegible] Klinische Diagnostik

soluble barium salt) free or *combined with organic matter or a volatile base.*

The amount of hydrochloric acid combined with organic base is small in normal cases but in the carcinoma cases it is clear from the results of this and the succeeding method that there is a certain amount of acid neutralised by volatile or organic bases present in the gastric contents.

(*e*) *Total free and combined organic acids.*—An attempt was made to investigate this quantity by the following method. Ten cubic centimetres of the filtered gastric contents are taken and titrated with phenol-phthalein as in (*a*) for determination of total acidity. In this process, as mentioned above, there are neutralised, the hydrochloric acid, the organic acids, and the acid salts (such as acid phosphates). The neutral solution is next evaporated to dryness, incinerated, taken up with hot water, and boiled. In this process the sodium chloride formed from the hydrochloric acid remains unaltered and the neutral salts formed from the acid salts remain neutral; but the neutral organic salts formed from the organic acids, as well as any neutralised organic salts originally present in the gastric contents, are converted into carbonates and give an alkaline reaction. Accordingly the total organic acids present in the gastric contents, whether free or combined, are given by now titrating the solution with excess of acid, boiling to remove carbonic acid and back titration with deci-normal alkali. The results of this method show a very low amount of organic acids in both normal and malignant cases; in fact, in the latter the results are often negative, indicating the presence in the gastric contents of inorganic acid united with organic bases.

The presence under such pathological conditions of such compounds of organic bases with inorganic acid is in itself of high interest and requires further investigation. The small quantity of material obtainable in each case renders it difficult to determine the nature of the bases present but it has been shown not to be ammonia, and that it is not proteid is shown by the controls and the acidity given by the other methods.

(*f*) *Concentration of free hydrogen ions in the gastric contents.*—The usual methods of determining the acidity of a solution give only the potential or total acidity—that is, the amount of standard alkali which must be added in order to render it neutral to an indicator. This is quite a different quantity to the effective acidity, for chemical purposes, of the solution. For example, titration in presence of an indicator will show that a deci-normal solution of the hydrochloric acid and of an organic acid, such as acetic acid, are equal in acidity. This is not, however, the case, the effective acidity of the solution of acetic acid is only about 3 per cent. of that of the hydrochloric acid. The effectiveness as a chemical agent of any acid is proportional to the degree of its dissociation into its ions. For example, hydrochloric acid in the neighbourhood of such concentrations as are found in the gastric contents is over 95 per cent. dissociated into its ions and is correspondingly effective as an acid, while acetic acid in similar concentration is only dissociated to the extent of about 3 per cent. and is correspondingly weakened in its activity as an acid, and the same is true of all the other organic acids occasionally present in the gastric contents.

In the process of titration, as the fraction of dissociated acid is combined with alkali, fresh quantities of previously undissociated acid become dissociated and the indicator does not show neutrality until these also have been combined with alkali. Hence the process of titration does not show the amount of dissociated acid free for chemical work at the commencement of titration. This is, however, the really important thing to determine and to do so some method must be employed which, without altering the condition of dissociation of the acid solution, gives its power of doing chemical work.

A method usually employed in physical chemistry is that of testing the velocity with which the acid solution inverts a solution of cane sugar, or more conveniently a solution of methyl acetate, which becomes changed into methyl alcohol and acetic acid at a rate proportional to the concentration of the hydrogen ions in the solution, which is the real measure for the effective acidity of the solution. The use of the methyl-acetate method not only gives the effective acidity of the solution but by comparison with the total acidity given by titration in presence of a delicate indicator such as phenol-phthalein shows in what degree the acidity is due to hydrochloric and in what degree to organic acids. The method was first used in the case of the gastric contents by F. A. Hoffmann[11] at the suggestion of Ostwald.

The determinations have been carried out by us as follows. Ten cubic centimetres of the gastric contents are taken in a small corked Erlenmeyer flask, 0·5 cubic centimetre of the methyl acetate is added, and five cubic centimetres of the mixture are titrated at once with deci-normal alkali, free from carbonate, using phenol-phthalein as indicator. The flask is then placed for a definite time in a thermostat at a temperature of 45° C. (we have used a period of eight hours but a shorter period would suffice) and at the end of the period the contents of the flask are titrated again; the increase in the amount of alkali required for neutralisation gives the amount of acetic acid set free by the action of the hydrogen ions of the gastric contents during the interval and hence an indication of the concentration of these ions. A simple calculation then gives the concentration of the hydrogen ions. For the purposes of this calculation the total amount of acetic acid capable of being set free from the 0·5 cubic centimetre of methyl acetate added is required and to obtain this a control is made in which deci-normal hydrochloric acid is allowed to act on methyl acetate in the same concentration until the titration gives a constant figure for five cubic centimetres of the mixture. This figure can be obtained once for all for any series carried out about the same time with the same sample of methyl acetate.[12]

A comparison of the results given in the table of the titrations for acetic acid, formed from the methyl acetate in the cases of malignant disease, as compared with those in the case of the normal control specimens, demonstrates clearly the value of the method and shows the great contrast between the cases of malignant disease and the others.

The equation giving the velocity constant of the reaction (K), which is proportional in each case to the concentration of the hydrogen ions, takes the form—

$$K = \frac{1}{t} . \log \frac{A}{A - x},$$

where t is the time, expressed in minutes, A is the amount of methyl acetate available for hydrolysis in the beginning, and x the amount of methyl acetate hydrolysed at the end of the time t. The column in the table gives the values of $K \times 10^5$, to which the concentrations of hydrogen ions or the effective acidities are proportional, and the last column gives the percentage concentration reckoned as effective hydrochloric acid, by comparison with the constant for a deci-normal solution (0·365 per cent.) of hydrochloric acid.

DEDUCTIONS FROM THE RESULTS.

1. The *total acidity* in malignant disease, wherever situated, is, as a rule, very low. In the 17 cases recorded the total acidity only rises above 0·1 per cent. in four cases (Nos. 5, 6, 11, and 16) and reaches the normal amount of approximately 0·28 per cent. in one case only (No. 16). In the great majority of the cases one or two drops of deci-normal alkali added to ten cubic centimetres is sufficient to render the reaction alkaline to phenol-phthalein. In the few cases where the total acidity rises above a trace only the other tests demonstrate that the reaction is not due to free hydrochloric except in minute traces.

2. The "di-methyl" indicator shows entire absence of acidity in nine out of 16 cases in which it was applied and in the remaining cases gives very low values approaching half-way towards normal in only one case (No. 5).

3. The Günzburg test shows entire absence of free hydrochloric acid in 11 out of 17 cases and in the remaining cases the quantitative use of the test shows that with one exception (Case 5) the amount of hydrochloric acid present was only a minute trace (from 0·0036 to 0·0109 per cent.). Case 5 was the only one which had an appreciable amount of free hydrochloric acid and even here the amount present was less than one-fifth the normal quantity.

4. The Mörner-Sjöqvist method gave, as a rule, low results, but in Cases 11, 16, and 17 much higher results were given than by the other methods. There is little doubt that this result arose in those cases from the presence of salts of inorganic acids with organic bases and not to hydrochloric acid either free or loosely combined with proteid.

---

[11] Verhandlungen des Internationalen Medicinischen Congresses, 1890, Abtheilung v.

[12] The methyl acetate should be as pure as possible, give practically no acetic acid on titration alone, and a control, as indicated above, should be carried out at intervals, if the series of experiments is a prolonged one.

† Total amount hydrolysed in 24 hours, 31·6 cubic centimetres; in 48 hours, 31·7 cubic centimetres, leaving 26·9 as total available amount of acetate hydrolysable.

5. The presence of inorganic acid combined with organic base is shown by the zero or negative value obtained on incineration with excess of alkali in the attempt to determine the amount of organic acid.

6. The methyl-acetate inversion method shows clearly what small traces of effective acid are present as compared with the normal cases. In all the cases tested the concentration of hydrogen ions never exceeds one-fifteenth part of the normal amount and in the majority of cases sinks incomparably lower even than this low fraction.

7. After removal of the growth, as far as observations have gone, there is not a reappearance of acid. This tends to show that there is a persistence of those conditions in the body tending to favour the re-formation of new growths, but the subject requires more extended observation.

PROBABLE CAUSE OF THE ABSENCE OF THE ACID.

The cause of the absence of the acid from the gastric contents in malignant disease is not yet determined. Various points require elucidation, such, for example, as whether the oxyntic cells are atrophied, whether the acid secretion recurs after removal of the growth, whether any toxic substances are in circulation in the blood which paralyse the activity of the oxyntic cells, and whether the degree of alkalinity of the blood plasma is altered in malignant disease.[13]

A study of the alterations in the alkalinity of the blood seems at present to be one of the most hopeful lines of research on the subject but such observations are most difficult to carry out. For it is not the total alkalinity of the blood which is the determining factor in the power of the oxyntic cells to separate a fluid of acid reaction due to free hydrochloric acid from the blood plasma, but rather the effective concentration in hydroxyl ions and hydrogen ions respectively in the sense indicated above in speaking of the methyl-acetate method

In order that hydrochloric acid may be separated by the cells of the gastric glands it is necessary that there must be some concentration of hydrogen ions, however low that concentration may be, in the circulating plasma Further, the concentration of hydrogen ions in the plasma being very low it follows that any agency which depresses that concentration, such as increased alkalinity of the plasma, must increase the difficulty and lessen the rate of separation of acid.

The reactions to indicators of the plasma show that it is a fluid which is, at the same time, alkaline and acid; in other words, [illegible]
Thus, it is *ac* [illegible]

[13] Observations upon this point are now being made.

so low that it cannot be estimated by such a method as methyl-acetate inversion or by any physical method at present known. It is accordingly difficult, without some new method of attack, to investigate the effective acidity of the blood and it is probable that in the end some physiological method alone, some application, for example, of the effect of minute quantities of acid or alkali upon the rate of growth or activities of living cells, will furnish a delicate enough test for such measurements of reaction as are here required.

We are hence at present without a method delicate enough to show us how the concentration of the hydrogen ions is varying in the blood plasma in health or in conditions such as malignant disease; but if we suppose that the failure or reduction in quantity of the acid is an indication *through the mechanism of the oxyntic cell* that the concentration of the hydrogen ions in the blood of carcinomatous patients is decreased, and the concentration of the hydroxyl ions increased, then we have indications from analogy with the changes which occur in other growing cells under like conditions that such a change would probably give rise to increased cell growth and division. Thus, Loeb[14] has shown that addition of one cubic centimetre of deci-normal caustic soda solution to 100 cubic centimetres of sea water, that is, an addition of only 0·04 gramme per litre, increased the development and growth of the eggs of the sea urchin at such a rate that one could scarcely believe that the two sets of eggs belonged to the same culture. It is only a trace of additional alkali which causes the increased growth, more than a trace stops it entirely.

Now, given a potential tendency to a typical cell growth and mitosis, to reversion to the sexual type of cell reproduction, it is possible that an increased concentration of hydroxyl ions and diminished concentration of hydrogen ions, would form just the necessary chemical stimulus to start a new growth and determine its continuance and exuberance when started. It might be urged that the testing of such a view was exceedingly simple, merely by the administration of acid, so as to give hydrogen ions to the blood plasma, but the matter is not so simple as it at first sight appears. It certainly is indicated that some attempt should be made to modify the reaction of the blood plasma and if possible to restore the acid-secreting function of the oxyntic cells and we are at present making attempts in this direction. But to keep permanently altered, even by continued therapeutic action, the reaction of the blood plasma is by no means easy of attainment. The reaction of the blood is determined by the agency of the liver and kidney cells, and if these have become set at a definite wrong level of action, all the regulating mechanism of the body is then at work against change of the reaction by therapeutic means. When acid is administered urea is taken and broken up in the body and ammonia obtained which is used to neutralise the administered acid. Hence it is only with large and continued doses of acid, and on approaching the limits of acid intoxication, that any diminution in alkalinity can be hoped for and as soon as the administration of acid is slackened the acid is neutralised by more ammonia obtained from oxidised proteid. Thus, even admitting that the diminished acid secretion is due to diminished concentration of hydrogen ions in the blood plasma, we are still face to face with the problem of how to maintain that hydrogen ion concentration in the blood plasma permanently at a higher level against the competition of the kidney and other cells in the body which are all the time tending to reduce it to its old vicious level.

LATENT PNEUMOTHORAX.

By B. CROSSFIELD STEVENS, M.D., M.S. DURH., F.R.C.S. EDIN.

TEXT-BOOK descriptions of pneumothorax divide the *causes* into phthisical and traumatic and the *varieties* as open, closed, and valvular. The following notes of a case under my care go, I think, to prove that in an asthmatic subject (where there is sure to be emphysema as well) one of the distended air vesicles on the surface of the lung may also attenuate its pleural covering and that this condition plus some slight extra strain may cause the vesicle to burst and allow air to enter the pleural cavity. In the museum of St. Thomas's Hospital, London, is a specimen which I obtained from a post-mortem showing two such vesicles; one was of the size of a hen's egg and the other (joined to it) of that of a pigeon's egg. Had either of these ruptured during life I take it that one would have had a latent pneumothorax to deal with. In Mr. R. Bevan's case[1] a sudden nipping of the edge of the lung with the air vesicles in an over-distended condition was probably the cause of the pneumothorax. In Mr. E. F. Coghlan's case[2] it seemed to be a phthisical patient and the recovery from the lesion was rapid, though no quicker than a non-phthisical case ought to be with proper rest and care.

The case which I wish to quote was that of a young and energetic curate. His history is interesting and is as follows. On the morning of the day before I saw him he was taken ill at Y——. Previously to this attack he had felt quite well but had been thoroughly tired out the day before from considerable manual exertion (he was a keen gardener). On the morning in question he was kneeling in church and experienced a feeling of discomfort round the heart; this was greatly increased on attempting to move. Owing to considerable pain round the heart he was given brandy but with no relief. He then took a cab to see a medical man who called it "wind round the heart" (meaning distension of the stomach) and gave him some carminative. Needless to say, this did no good. The only relief he could obtain was by lying on the sofa on his left side. Feeling relieved he got up and walked away but in a few minutes he was as bad as ever and took refuge in a station waiting-room and was at once relieved by lying down again on the left side. After a while he returned to his medical adviser and asked him to examine his chest. The verdict was "indigestion" and some purgative pills were prescribed. After this he walked about Y—— in great discomfort until his train started for M——, a run of over an hour. He found it difficult to climb the hill to his house but suffered no actual pain as was the case in the morning. Having had practically no food since breakfast he made a hearty supper and went to bed. During the night he got very little sleep and sent for me. I saw the patient within 24 hours of the onset of the illness and found him in bed lying on his left side, in great distress from dyspnœa but not cyanosed. The pulse was quick but good; there was no rise of temperature. There was no distension of the stomach but the heart was nowhere to be found in the left chest. The right lung was working vigorously and was full of rhonchi and emphysematous wheezing. The left side of the chest was quite still and fixed and the lower half appeared bulged out; the general appearance of the chest was barrel-shaped. The voice and breath sounds were absent on the left side. The heart was beating in the epigastrium and to the right of the xiphoid cartilage. On the left side also the percussion note was hyper-resonant from the first with slight dulness at the base behind, the axillary hyper-resonance being the more pronounced. Bruit d'airan was very pronounced and the metallic tinkling was as of water dropping in a cavern. The treatment prescribed was rest in bed, a sedative mixture, and an anti-flatulent diet and alcohol. The breath sounds began to return in less than a week and the heart very gradually came back to the left. In three days the patient was comfortable on his right or sound side. In ten days he was up and walking about but breathless on slight exertion. In just under three weeks he went to Cornwall—his native air—and after staying there for three weeks he was quite well. Of his visit to Cornwall he says: "I got steadily better day by day and after ten days at home could walk up the steepest hill or cliff as fast as any one and without discomfort. A sudden jolt or jar, however, was unpleasant. When there a sudden fall in temperature one night when the windows were wide open in the bedrooom brought on an attack of asthma which lasted six hours." I have forbidden him to cycle up hills or to do heavy gardening or lifting and a year later I hear that he is in good health.

Remarks.—This patient is an asthmatic and his sister is described as a martyr to asthma. As a curate he has been taught to use the lower part of his lungs in phonation so as to save his larynx. This has no doubt been an extra strain on his already over-distended lungs. The treatment in these cases is the expectant one. . Put the patient under the best hygienic surroundings, give alcohol if there is distress; the nutriment must be easily assimilable and not such as might give rise to flatulent dyspepsia. Of drugs iodide and arsenic are useful at first, and some petroleum emulsion later.

Lancaster.

THE EFFECT OF CERTAIN BATHS AND FORMS OF ELECTRICITY ON THE BLOOD, BLOOD PRESSURE, AND METABOLISM;

WITH REMARKS ON THEIR THERAPEUTIC USES.

BY WILLIAM BAIN, M.D. DURH., M.R.C.P. LOND.;
WILFRID EDGECOMBE, M.D. LOND.,
PHYSICIAN TO THE HARROGATE INFIRMARY
AND
HERBERT FRANKLING, M.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY MEDICAL OFFICER TO OUT-PATIENTS, HARROGATE INFIRMARY.

THE following investigation was undertaken to ascertain the effect of certain baths and electrical procedures in use at Harrogate on the blood, on the blood pressure, and on metabolism as indicated by variations in the urinary constituents. It was primarily intended to investigate these points with reference to the more recently introduced electrical "baths" but it was thought that the usefulness of the research might be enhanced by extending it to include some of the other baths which have been long in use with the object of determining whether the physiological results obtained would furnish a rational basis for their therapeutic application. The subjects of the experiments were the authors themselves and the observations extended over 40 days. Their health was normal throughout; the results must therefore be regarded as purely physiological.

Points examined.—These consisted of the determination of the total daily excretion of urea, uric acid, sulphates, phosphates, chlorides, and acidity, the estimation of the hæmoglobin and red corpuscles, the enumeration of the leucocytes, and the measurement of variations in the blood pressure.

Methods adopted.—For the determination of urea the hypobromite method was adopted, Gerard's instrument being chosen. Uric acid was estimated by the Gowland-Hopkins' process; sulphates by the barium chloride method; phosphates by titration with uranium acetate; chlorides by Allen's modification of Mohr's method for the first three [illegible] of the red corpuscles was estimated by Oliver's capacity tube. The leucocytes were counted in the Thoma-Zeiss chamber, the diluting fluid being acetic acid 0·3 per cent. with methyl violet, and the amount of dilution 1 in 25. Blood pressure was determined by means of Oliver's hæmodynamometer. The total urine of the 24 hours was collected daily for the estimation of its constituents. The blood was examined once a day, the time chosen being immediately after rising in the morning when the blood is at its most constant point, before being disturbed by bath, exercise, or breakfast. It was also occasionally examined immediately before and after the baths, as will be detailed presently.

Diets: Subject A (weight 11 stones 1 pound 7 ounces).—Breakfast: bacon, 2 ounces; egg, 1; toast, 2 ounces; coffee, 15 ounces. Lunch: meat, 2 ounces; bread, 2 ounces; cheese, ½ ounce; biscuits, 2 ounces; banana, 2 ounces; water, 10 ounces. Tea: tea, 8 ounces; biscuits, 2. Dinner: meat, 4 ounces; bread, 2 ounces; cheese, ½ ounce; biscuits, 2; apple, 1; water, 10 ounces. Coffee; 4 ounces. Bed-time: water, 10 ounces.

Subject B (weight 12 stones 12 pounds).—Breakfast: egg, 1; toast, 1½ ounces; coffee, 10 ounces. Lunch: meat, 2 ounces; ham, 1 ounce; toast, 1½ ounces; cheese, 1 ounce; celery; milk, 10 ounces. Tea: tea, 12 ounces; milk biscuits, 4. Dinner: meat, 3 ounces; toast, 1½ ounces; cheese, ½ ounce; apple, 1; water, 10 ounces. Bed-time, water, 10 ounces.

Subject C (weight 13 stones 3 pounds).—Breakfast: bacon, 2 ounces; egg, 1; bread, 1½ ounces; tea, 20 ounces. Lunch: meat, 2 ounces; cheese, ½ ounce; bread, 1½ ounces; water, 10 ounces. Tea: tea, 8 ounces; biscuits, 3. Dinner: meat, 6 ounces; cheese, 1 ounce; bread, 2 ounces; apples, 2; water, 20 ounces.

Normal standards of the three subjects.—Before determining these and to arrive at a condition of approximate equilibrium the diet was taken for a week before testing. Estimations were then made daily for four days (in the case of Subject C. for five days) and the average taken, the result being shown in Table I.

THE D'ARSONVAL HIGH-FREQUENCY CURRENT.

The extent to which this form of electricity has been used [illegible] the last few years rendered the [illegible] cal action on metabolism a [illegible]. In examining the literature of the subject we were unable to find any detailed statements as to its effects in this direction. The following facts appear to have been established. Apart from its effects on motor and sensory nerves the respiratory combustion is increased, there being an increased excretion of CO_2 under the current amounting to 37 litres per hour; a more active oxygenation of the blood takes place, leading to a plus heat production of from 79 to 127 calories per hour, the body temperature remaining normal; the excretion of nitrogen and P_2O_5 in the urine is increased. Nutrition is modified and a definite loss in weight varying from one to 28 ounces takes places during the passage of the current.[1] The statements of various observers regarding its effect on blood pressure are contradictory, some finding a rise in arterial tension and others a fall.

For the present investigation the current was administered by the method of auto-condensation (from 350 to 450 milliampères) for 30 minutes on four successive days, followed by the effleuve of maximum intensity obtainable without sparking, applied to the whole surface of the body in succession for 30 minutes on two consecutive days.

Effect on blood pressure.—The effect varied according to the mode of application. Auto-condensation produced a slight transient rise in arterial pressure of from five to ten millimetres of mercury, rapidly falling, however, to normal, the net effect appearing to be *nil*.

TABLE II.

Subject A.

		Mm. Hg.
Before current	Radial pressure (recumbent)	95
30 minutes' auto-condensation from 350 to 450 milliampères—

Before current	Radial pressure (recumbent)	110
30 minutes' auto-condensation from 350 to 450 milliampères—		
Immediately after ...	Radial pressure (recumbent)	118
5 minutes after	" "	110

The effleuve applied continuously to the whole surface of the body produced a distinct fall in blood pressure amounting to 10 or 15 millimetres of mercury. When applied, however, to the *abdomen* the pressure rose somewhat, though not to its original level. The duration of the fall in pressure after the current ceased *to* flow was variable but in no case prolonged. Sparking (from 100 to 150 milliampères) combined with gentle massage caused rapid hyperæmia when vigorously done and gave rise to a papulo-erythematous rash which disappeared after 36 hours. The effect of this form is to cause a more persistent fall of arterial pressure.

5 ,, afterwards	90	... .	10	13	10

Subject A.

		Mm. Hg.
Before sparking	Radial pressure (semi-recumbent) ...	96
After 15 minutes' auto-condensation and 15 minutes' sparking to limbs and body ...	Radial pressure (semi-recumbent) ...	85

It would thus appear that the divergent results on arterial pressure previously obtained may be due to the different forms of current employed, auto-condensation causing a temporary rise and the effleuve a decided fall, both results having been obtained on all occasions. From the above table it will be seen that a slight loss of weight, varying from one to four ounces, occurred in normal subjects, thus corroborating Nightingale's results.

Effect on the blood.—Observations on the blood immediately before and after the application of the current were not made. The morning observations, however, showed an increase in the amount of hæmoglobin during the days on which the current was taken over the average of the preceding days on which no current was applied. The corpuscles, on the other hand, were relatively diminished on the bath days, consequently there was in both the subjects of experiment an increase in the hæmoglobin "value" of the corpuscle; in one case (Subject C) from 1·01 to 1·025 after six applications and in the other (Subject A) from 0·99 1·025 after nine applications.

Effect on metabolism.—The effect on the urinary constituents is shown in the following table:—

TABLE IV.—*Subject C.*

—	Average of five preceding days.	Average of four days' auto-condensation, 30 minutes daily, from 350 to 400 milliampères.	Average of two days' effleuve, 30 minutes each day.
Quantity	1167 c.c.	1197 c.c.	1355 c c.
Urea	27·62 grammes.	33·39 grammes.	32·85 grammes.
Sulphates	2·13 ,,	2·50 ,,	2 88 ,,
Uric acid	0 656 ,,	0·718 ,,	0 769 ,,
P_2O_5	2·32 ,,	2·46 ,,	2 61 ,,
Chlorides	13·29 ,,	10·75 ,,	15·37 ,,
Acidity in terms of oxalic acid	3·56 ,,	3·25 ,,	2·84 ,,

It will be seen that the application of the current in these two forms in succession produced a marked increase in the excretion of urine, an increase in urea, uric acid, sulphates, and phosphates, and a marked diminution in acidity. In Subject A the results were in the same direction though to a somewhat less extent. It would thus appear that the passage of the high-frequency current has a distinct effect upon the metabolic processes, a result which must be tentatively explained as the outcome of increased tissue change. It may be mentioned as a point of interest that both subjects were struck by the fact that the effleuve to the abdomen excited marked peristaltic action, leading to the free passage of flatus for some hours after exposure to the current and in one subject to repeated diarrhœa. This accords with the results of Crombie and Bokenham[2] on the effect of the effleuve in promoting contraction of the stomach in cases of dilatation. Further, the rise in blood pressure which results when the effleuve is applied to the abdomen is in all probability due to stimulation of the splanchnic vessels.

CONSTANT CURRENT AND SINUSOIDAL CURRENT IMMERSION BATHS.

Sinusoidal current.—This bath was taken on three successive days. The water used was a mild alkaline sulphur water derived from the Beckwith Spring. It was given at a temperature of 98° F., the duration of the bath being 20 minutes, during which time the alternating current (60 milliampères) was passing through the water.

Effect on blood pressure.—No effect was observed other than that usually found as the result of an ordinary sulphur bath at a temperature of 98°—viz., a fall of about 15 millimetres of mercury which returned, however, to the normal immediately after the bath, for example:—

TABLE V.

Subject B.

		Mm. Hg.
Before bath	Radial pressure (recumbent)	95
Bath: Beckwith sulphur water (98°), sinusoidal current, for 60 milliampères, 20 minutes:—		
In bath 10 minutes	Radial pressure (recumbent)	85
,, ,, 15 ,, ...	,, ,,	80
Immediately after bath ...	,, ,,	95

Effect on blood.—This was practically *nil*, no changes worthy of note being observed.

Effect on metabolism.—The sinusoidal current produced no distinctive change in the urinary constituents.

Constant current.—This bath was taken on four successive days, the same (Beckwith) water being used at a temperature of 98° F.; the duration of the bath was 20 minutes with a current of 200 milliampères.

Effect on blood pressure.—No change in the blood pressure before and after the bath was observed. A warm sulphur bath at 98° has usually the effect of reducing the blood pressure for a variable period after the bath and the effect of both sinusoidal and constant currents appears to be to abolish this fall and to maintain the pressure.

Effect on metabolism.—In contradistinction to the sinusoidal the constant current determined a slight increase in the excretion of urea and uric acid.

LIGHT AND OZONE BATH.

This bath is essentially an electric-light bath with the addition of the high-frequency current and the inhalation of an ozonised atmosphere. It consists of a large cabinet in which the patient lies on a glass shelf, exposed to the rays from a series of incandescent electric lamps suspended about 18 inches above the body, the eyes being protected from the glare by the interposition of a green shade. The temperature of the interior of the cabinet is usually about 100° F., that of the surface of the body exposed to the heat being about ten degrees higher. During the bath a continuous manufacture [illegible] means of a high-frequency current [illegible] ush electrode placed in a corner of [illegible] of the bath is usually 25 minutes, during the last ten of which a high-frequency current is passed through the body from a glass vacuum electrode held in the hand. After the bath a sponge down is given preparatory to cooling off.

---

[2] THE LANCET, Oct. 18th, 1902, p. 1043.

A good deal of work has been done on the physiological effect of electric light baths, notably by Kellogg[3] and M. Cleaves,[4] but, as in the bath under consideration, the two additional factors of the high-frequency current and the inhalation of ozone are introduced the results are not strictly comparable. Kellogg states that in the electric-light bath, sweating sets in earlier and is more profuse than in any other form of hot bath; that the elimination of CO_2 is greater; that there is a rise in body temperature during the bath; that there is an increase in the blood count—especially of the red cells—of from 10 to 20 per cent., which appears within half an hour and persists for some time and that in cases of marked anæmia the increase is usually permanent if daily application be made. Cleaves states that in some cases the hæmoglobin and corpuscles are increased but not in others. The bath was taken by two observers; by one four days in succession, by the other three days.

Effect on blood pressure.—The blood pressure always showed a great fall—greater than is usually obtained by exposure to a similar degree of heat in any other form of hot bath. The fall, however, is of brief duration, disappearing soon after the bath, e.g.:—

TABLE VII.

Subject A.

		Mm. Hg.	Body temperature.
Before bath	Radial pressure (sitting) ...	97 ...	96° F.
„ „	„ „ (recumbent)	87 ...	—
Bath; temperature of cabinet, 100° F.; that of surface of body exposed to light, 110° F.—			
In bath 5 minutes ...	Radial pressure (recumbent)	70 ...	—
„ „ 10 „ ...	„ „ „	60 ...	—
„ „ 15 „ ...	„ „ „	55 ..	100·0° F.
High frequency current passed through body—			
In bath 20 minutes ...	Radial pressure (recumbent)	50 ..	100·2° F.
5 minutes after bath ...	„ „ „	75 ...	99 8° F.
10 „ „ „ ...	„ „ „	80 ...	—
25 „ „ „ ...	„ „ (sitting)	95 ...	99 0° F.
40 „ „ „ ...	... ...	...	98·6° F.

Effect on the blood.—The immediate effect on the blood taken before and after the bath was to cause an increase in the number of erythrocytes which attained its maximum about half an hour after the bath.

TABLE VIII.

Subject A.

	Red corpuscles.
Before bath	98 per cent.
Immediately after bath	95 „
30 minutes after bath	104 „

The morning examination of the blood showed that the series of baths caused a slight decrease in the amount of hæmoglobin and a marked decrease in the number of the corpuscles, with a consequent striking rise in the value of the corpuscle: in Subject A, from 0·99 to 1·045; and in Subject B, from 0·986 to 1·07.

TABLE IX.

Subject B.

	Average of four free days.	Average of four light and ozone baths.
Hæmoglobin	107·8	105·3
Erythrocytes	109·2	98·3
Value	0 986	1·07

Subject A.

	Average of all free days (10).	Average of free days immediately preceding light and ozone.	Average of three light and ozone baths.
Hæmoglobin ...	94·3	97·0	95·2
Erythrocytes ...	94·1	98·0	90·7
Value	1·00	0·99	1 045

This conspicuous result raises the question, to which of the factors concerned is it to be attributed? It will be shown that the Dowsing radiant heat, which is essentially an incandescent electric-light bath, causes a fall in the value of the corpuscle—hence the rise obtained must be attributed to some other factor; and as the high-frequency current alone causes a slight but not marked rise the ozone remains the probable cause. To determine this point exposure to the ozonised atmosphere within the cabinet for 25 minutes daily was undertaken on three successive days without the electric light and the high-frequency current, and the blood was examined each morning and for three days previously. The result showed a rise in value from 0·986 to 1·043, thus clearly proving ozone to be the factor concerned. The blood examined before and after inhalation of the ozone showed an immediate rise in value, in one case of 7 per cent. after 35 minutes in the cabinet, in another of 4 per cent. after 25 minutes.

TABLE X.

Subject C.

	Value of corpuscle.

Before exposure to ozone ...	100	98	0·98
Immediately after 35 minutes' exposure	100	105	1·05
Subject A.			
Before exposure to ozone ..	98	95	0 97
Immediately after 25 minutes' exposure	98	99	1·01

The suggestiveness of this result in the treatment of [illegible] need no comment. [illegible] ence to Table VII. will show [illegible] raised about 2° F. during the bath. The effect of these baths on the urinary output appears to be slight. They produced in both subjects a diminution in the quantity of urine passed, a slight fall in the excretion of urea due probably to loss in the perspiration and a slight rise in the excretion of uric acid and phosphates, the sulphates being unchanged.

SUPERHEATED AIR BATHS—DOWSING-GREVILLE.

The Dowsing and Greville systems of applying very high temperatures to the [illegible] are too well known to req[illegible] Dowsing being a luminous heat supplied by ordinary incandescent lamps and the Greville a non-luminous heat engendered by the passage of an electric current through a large number of fine wires. The object of this investigation was to determine the effect of these baths on metabolism and the advantages, if any, possessed by one system over the other.

Dowsing radiant heat bath.—This bath was taken by two observers, A. and C., in both cases on four successive days and at a temperature of from 280° to 300° F. applied to the whole body for 30 minutes.

Effect on the blood pressure.—Like all hot baths the Dowsing produces a marked fall in arterial blood pressure but, as will be seen on comparison with the results obtained in the Greville bath, the fall is greater at a lower temperature when the factor of light is introduced.

TABLE XI.

Subject C.

[3] Cohen's System of Physiologic Therapeutics, vol. ix.

[4] New York Medical Journal, 1899.

Effect on the blood.—As will be seen in the above table the immediate effect on the blood is to cause a primary diminution in the number of corpuscles with a subsequent increase after the bath. The remote effect on blood examined on successive mornings is a marked reduction in the value of the corpuscle, in one case from an average of 1·00 to 0·973 (Subject A), in another from 1·002 to 0·957 (Subject C), as the result of 4 baths.

Erythrocytes	94·1% ...	92·5%	Erythrocytes	101·0% ...	100·0%
Value	1·00 ...	0·973	Value	1·002 ...	0·957

Effect on urinary constituents.—A marked reduction in quantity of urine and a slight reduction in urea and acidity were observed, and a marked increase in uric acid output and in phosphates.

TABLE XIII.—*Subject A.*

—	Average free days.	Average Dowsing baths.
Quantity	1251 c.c.	848 c.c.
Urea	32·01 grammes.	30·41 grammes.
Sulphates	2·21 ,,	2·19 ,,
Uric acid	0·687 ,,	0·776 ,,
P_2O_5	2·41 ,,	2·86 ,,
Chlorides	9·77 ,,	8·44 ,,
Acidity	3·22 ,,	2·54 ,,

Greville bath.—This bath was taken by Subject C. on four successive days at a temperature of 300° F. for 30 minutes. This temperature was more comfortably borne than a temperature of 280° in the Dowsing bath, the scorching sensation experienced in the latter being notably absent. Sweating in this Subject (C) began sooner and was more profuse in the non-luminous heat than in the luminous heat.

The effect on blood pressure is shown in the following table:—

TABLE XIV.

Subject C.

		Mm. Hg.	Body temperature.
Before bath	Radial pressure (sitting) ...	115 ...	97·4° F.
,, ,, ...	,, ,, (recumbent)	105 ...	—
Greville bath: reaching	250° F. in 13 minutes ...	— ...	—
,, ,, ,,	295° F. in 15 ,, ...	— ...	97·6° F.
,, ,, ,,	302° F. in 27 ,, ...	— ...	99·8° F.
In bath 32 minutes...	Radial pressure (recumbent)	80 ...	—
15 minutes after bath	,, ,, (sitting) ...	90 ...	98·6° F.
30 ,, ,, ,,	,, ,, ,, ...	100 ...	—
80 ,, ,, ,,	,, ,, ,, ...	112 ...	—

It will be seen that the reduction in blood pressure at a temperature of 300° F. in the Greville bath is not so great as that caused by a temperature of 280° in the Dowsing.

Effect on the blood.—A similar immediate diminution in the volume of the corpuscles took place during the bath with a subsequent rise about half an hour afterwards. The remote effect on the value of the corpuscle, however, differed from that obtained in the Dowsing bath, for a notable increase in hæmoglobin value was observed as the result of the four baths, the average value rising from 0·99 on the days prior to the bath to 1·02 on the bath days.

Effect on metabolism.—The following table gives the results obtained.

TABLE XV.—*Subject C.*

—	Average of free days (before bath).	Average, Greville baths.
Quantity	1190 c.c.	1320 c.c.
Urea	29·25 grammes.	29·62 grammes.
Sulphates	2·06 ,,	2·96 ,,
Uric acid	0·654 ,,	0·729 ,,
P_2O_5	2·17 ,,	2·45 ,,
Chlorides	11·13 ,,	11·65 ,,
Acidity	3·57 ,,	3·14 ,,

Contrasting these results with the Dowsing bath it will be seen that the quantity of urine is markedly increased. Now an increase of urine is usually accompanied by an increased excretion of urea, which, however, as the result of the baths, is not apparent in the table. There was, therefore, probably a relative diminution in the quantity of urea excreted by this channel. The uric acid was markedly increased, as occurred with the Dowsing bath, and an increase was observed in the sulphates and phosphates. It will therefore be seen that the great circulatory changes induced by both forms of baths have a marked effect in modifying the metabolic processes.

Comparing the results obtained from the two baths respectively it would appear that the effects common to both are an initial reduction of the volume of the corpuscles with a subsequent increase and a marked plus excretion of uric acid. On the other hand, the most important points of dissimilarity lie in the reduction of hæmoglobin value of the blood by the Dowsing bath and its increase by the Greville bath, and in the greater fall in blood pressure induced by the former than by the latter at corresponding temperatures. The explanation of these points of difference is not obvious. The only factor present in the Dowsing system, beyond those at work in the Greville system, is the presence of the light rays; these, however, do not impinge directly upon the skin —a layer of lint intervening through which they must pass before reaching the surface.

It has been shown by one of us[5] in experiments performed on the dog that luminous heat causes a greater reaction at a lower temperature and raises the body temperature both local and general, to a greater degree than the non-luminous heat. The hind limb of a dog was exposed to a temperature of 250° in the Dowsing box for 45 minutes, at the end of which time the temperature of the venous blood returning from the limb had risen from 95·8° to 111°, and the general temperature of the body from 95·8° to 99·3°. A similar experiment performed with the non-luminous heat by the Greville system at a temperature of 300° for 45 minutes (i.e., 50° higher than the Dowsing bath) caused a rise of only 6·6° in the venous blood returning from the limb, and a rise of 1·8° in the general body temperature.

BERTHE AND VICHY BATH.

This bath was taken by Subject A on four successive days. It was investigated, since it is a bath in frequent use in this country and on the continent for chronic gout and other nutritional disorders. The bath consists of a preliminary exposure to steam heat at a temperature of 120° F. for 15 minutes in the Berthe box—a closed cabinet in which the patient sits with his head protruding through an aperture in the top. This proceeding is then followed by massage administered for 20 minutes in the recumbent posture under a spray douche of from 98° to 100° projected upon the patient from a bracket suspended above the table and pierced by innumerable pin-holes. A needle douche begun at 98° and gradually reduced to cool or cold completes the bath, after which the patient rests for half an hour or more till perfectly cool.

Effect on blood pressure.—The following table will illustrate the changes which take place in blood pressure:—

TABLE XVI.

Subject A.

		Mm. Hg.
Before bath	Radial pressure (sitting)	95
After 15 minutes in steam box at 120° F.	,, ,, ,, ...	75
After 20 minutes' massage and one minute in needle bath reduced from 98° to 55° F.	,, ,, ,, ...	110
5 minutes after	,, ,, (recumbent)	85
15 ,, ,, ...	,, ,, (sitting)	107
30 ,, ,, ...	,, ,, ,, ...	105

It will be seen that the net effect is a rise in blood pressure, which may help to explain the notably invigorating properties of this bath.

Effect on the blood.—The remote effect on the blood was to cause a slight rise in hæmoglobin value from 1·01, average on the three days prior to the baths, to 1·02, average on the four days on which the bath was taken.

Effect on metabolism.—The effect on metabolism was not marked, as might have been expected, a slight rise in the urea, sulphates, and uric acid being noted.

Quantity	1141 c.c.	1087 c.c.
Urea	32·18 grammes.	33·10 grammes.
Sulphates	2·06 ,,	2·19 ,,
Uric acid	0·686 ,,	0·695 ,,
P_2O_5	2·46 ,,	2·37 ,,
Chlorides	6·76 ,,	7·80 ,,
Acidity	3·05 ,,	2·95 ,,

PEAT BATHS.

The material for these baths is obtained from the moors in the neighbourhood of Harrogate and consists of peaty earth highly charged with organic acids and containing a small proportion of iron. It is mixed to the consistence of thick pulp and raised by steam to a temperature of from 98° to 104° F. The duration of the bath was 20 minutes: it was taken by Subject B. on three successive days. The main object was to ascertain its effect, if any, on metabolism. Its effect on the blood pressure and on the blood was found to be the same as that of plain water at the same temperature.

Effect on metabolism.—The effect on the urinary output was as follows. A marked diminution in the quantity of urine passed was noted and in the excretion of urea, the other constituents showing no distinctive change. (*Vide* Table XVIII.)

TABLE XVIII.—*Subject B.*

—	Average excretion of free days.	Average excretion, three peat baths.
Quantity	1206 c.c.	957 c.c.
Urea	33·51 grammes.	30·94 grammes.
Sulphates	2·03 ,,	1·96 ,,
Uric acid	0·501 ,,	0·494 ,,
P_2O_5	2·19 ,,	1·89 ,,
Chlorides	9·42 ,,	8·46 ,,
Acidity	2·82 ,,	2·27 ,,

THERMAL SULPHUR BATH.

The so-called thermal sulphur bath is the strongest form of natural sulphur bath administered at Harrogate and consists of the pure sulphur water, undiluted, raised to the required temperature by passing through a "therma" or heating apparatus of coiled tubing. It contains about 235 grains per gallon of total solids, consisting chiefly of chlorides and carbonates of sodium, calcium, and magnesium, the chloride of sodium being largely in excess and the carbonates forming relatively a very small proportion of the whole. Sulphur occurs in the bath in the form of sodium sulphydrate, amounting to about two grains per gallon, and as sulphuretted hydrogen gas, about two cubic inches per gallon. It is the staple bath at Harrogate and was investigated to determine whether any effect on metabolism could be detected as the result of a short series. It was taken by Subject C on four successive days at a temperature of 98° F. for 20 minutes. No appreciable effect was observed on the urinary constituents beyond a marked increase in the quantity voided, though possibly a more prolonged trial might be found to have a more distinctive influence.

SUMMARY OF RESULTS AND THERAPEUTIC INDICATIONS.

The high-frequency current since its introduction has been used in the treatment of a great variety of affections, both local and general. Among the general affections may be mentioned gout, chronic rheumatism, obesity, diabetes, neurasthenia and hysteria, anæmia and chlorosis, phthisis [illegible] on of the stomach, and chronic [illegible] ffections, skin diseases—such as [illegible] psoriasis, chronic eczema, acne rosacea, rodent ulcer, chronic callous ulcer, pruritus ani and vulvæ—and local affections of the nerves—such as sciatica, neuralgia, local neuritis—are frequently treated by this form of electricity. In the treatment of hæmorrhoids good results are obtained from its use.

The physiological action of the current in its general application tends to confirm its use in cases of nutritional disorders, such as chronic gout, chronic rheumatism, and obesity, by reason of the changes effected in blood pressure and the stimulus given to metabolism, as shown by the plus heat production, the plus excretion of urea, of uric acid, and of CO_2, and the loss of weight. The rise produced in the hæmoglobin value of the corpuscle points to its use in the above cases when anæmia is a prominent symptom and also as a useful adjunct in cases of simple anæmia and chlorosis. T[illegible] istriped muscle fibre excited by [illegible] the method in cases of atony [illegible] y also account for the striking results sometimes observed in the shrinking and disappearance of hæmorrhoids after repeated applications. The evidence for its real value in cases of diabetes and phthisis does not appear to rest upon a sufficiently large number of cases to carry conviction as to its superiority over other modes of treatment. With regard to its action in local affections of the nerves and skin the foregoing results offer no evidence for or against. In our judgment, after considerable experience of the methods, the results obtained from the local application of the current are, on the whole, more favourable than those obtained from its general use.

Electric immersion baths are used largely to induce restoration of contractile power in cases of muscular weakness or atrophy resulting from nerve lesions or essential muscular dystrophy; and in cases of neurasthenia and the latent form of hysteria. They are also useful as a general tonic measure in cases presenting no definite disease but suffering from slackness and want of tone. It is also claimed that they exercise a favourable influence in cases of chronic gout, with or without local manifestations of the disease. The fibrillary muscular contraction excited by the current furnishes a basis for its use in the first class of cases. To this muscular contraction is probably due the inhibition of the fall in blood pressure that would otherwise result from the effect of the warm bath; and this may account to some extent for the tonic and invigorating effect experienced after the bath. The results obtained on metabolism are not sufficiently striking to justify the frequent employment of these baths in cases of chronic gout unless the slight increase in elimination of urea and uric acid which followed the constant current may be considered an indication in this direction.

The light and ozone bath.—The introduction of the factors of the inhalation of ozone and the passage of the high-frequency current differentiate this bath from the ordinary electric-light bath. The striking results obtained on the hæmoglobin value of the blood point to its use in cases requiring sweating baths, in which anæmia is present, and further tend to show that the daily breathing for a stated time of air highly charged with ozone may be a useful auxiliary measure in the treatment of intractable cases of chlorosis and secondary anæmia.

The Greville and Dowsing baths are both used for much the same class of cases and their application may be considered under the head of general to the whole body and local to various parts. Touching their general application for the cure of diseases other than those affecting the joints, much more is claimed for them than we think can be substantiated. Thus they have been advocated for the cure of phthisis, chronic bronchitis, asthma, chronic kidney disease, heart disease, anæmia, dyspepsia, obesity, chronic alcoholism, skin diseases, and others, in each of which good results are said to have been obtained by one or other system. In some of these, as for instance, chronic kidney disease, the indications are clear for their use. In others, though a few cases of each are recorded as having derived benefit, the evidence is not sufficiently strong to warrant the supersession by these baths of better known and longer tried methods. It is in the chronic general diseases of which the prominent manifestation is arthritis that they are of most service, such as gout, rheumatism, arthritis deformans, gonorrhœal rheumatism, and especially in local affections of the joints, fibrous tissues, or nerves, such as chronic arthritis (gouty, rheumatic, traumatic), sprains, lumbago, sciatica, neuritis, and neuralgia. In these conditions better results are obtained and are probably to be accounted for by the profound alteration in nutrition which results from the marked variations in blood pressure produced and from the rapid changes that take place in the volume of the blood—alterations in nutrition which are in part evidenced by the considerable changes that occur in the excretion of urea and uric acid. Whether one system presents any real advantage over the other we are not prepared to say.

The Berthe and Vichy bath.—This is chiefly used in cases of chronic gout and rheumatism or in functional derangement of the alimentary tract. The initial lowering of blood pressure by the steam heat and its subsequent restoration after the full bath excite changes in the volume of the blood and changes in the relation of blood plasma to tissue fluid, effects which are aided by the vigorous massage administered and which result in the liberation of waste products from the tissues and their elimination from the body. The urinary constituents do not show as marked a change as has been previously found by us to result from a similar bath, the Aix douche,[6] in which there is no preliminary steam bath; and the difference is probably to be accounted for, at least in the case of urea, by the fact that some of the urea is carried off in the perspiration excited in the Berthe box.

The peat baths.—These are largely used in cases of chronic pelvic disorder of an inflammatory nature. Their action, which resembles that of a wide-spread poultice, materially aids in the absorption of effused products. They are also used for cases of chronic intractable rheumatism and gout and in local manifestation of these disorders, such as lumbago or sciatica. The results obtained by us are not conclusive enough to indicate strongly in which direction they are likely to be of service.

The thermal sulphur bath.—These baths are largely used at Harrogate in the treatment of gout, rheumatism, and functional derangements of the liver and also for their local action on the skin in cases of skin disease. In the former, as well as the latter, experience shows that they are of undoubted value, though their mode of action is by no means clear. Apart from their marked effect upon blood pressure, which has been previously shown,[7] this investigation proved nothing conclusive as to their influence on metabolism.

In conclusion, we wish to record our appreciation of the courtesy shown to us by Mr. A. H. Marshall, the chairman, and the late Mr. A. H. Davis, the manager of the Royal Baths, in affording us facilities for the use of the baths during the investigation.

A CASE OF EXTENSIVE CUTANEOUS DIPHTHERIA WITH AN EXAMINATION OF THE NERVOUS SYSTEM.

By CHARLES BOLTON, M.D., B.Sc. LOND., M.R.C.P. LOND.,
FELLOW OF UNIVERSITY COLLEGE; ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND TO THE NORTH-EASTERN HOSPITAL;
AND
DUNSTAN BREWER, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.R.C.P.S. LOND.,
ASSISTANT MEDICAL OFFICER AT THE HOMERTON FEVER HOSPITAL.

THAT diphtheria may attack a wound and lead to death by systemic poisoning is a familiar fact to every medical practitioner. The following case, however, presents several points of interest and from its extent and pathological characters vividly recalls to mind those cases of cutaneous diphtheria which were so common during the epidemics of the early part of the nineteenth century and concerning which the physicians of that period wrote but which are now comparatively rare and almost forgotten. We have, therefore, by the courtesy of Dr. E. W. Goodall, taken the opportunity of placing it on record.

Before Bretonneau's time Chomel[1] in 1759, Starr[2] in England and Samuel Bard[3] in America in 1771 had drawn attention to a membranous affection of the skin. Bretonneau in his first memoir gives examples of this affection and demonstrates that diphtheria in whatever locality it occurs in the body has everywhere the same characters. In 1828, during the epidemics at Sologne, Trousseau and Ramon[4] collected many cases which are described with great care. According to Trousseau diphtheria never develops on the skin unless the latter is previously deprived of its epidermis or ulcerated and the lesions which he has found to be affected with diphtheria are blisters, leech-bites, cuts, herpes, cracks of the breast, excoriations of the genital organs, of the ears, of the hairy scalp, of the nose, of the anus, and different wounds. He describes a case in which the vulva and the skin of the folds of the thighs were affected and which appears to have been very similar to our own. The commonest starting-point appears to have been in a blister applied to the neck.

With regard to the pathological appearances of a wound affected with diphtheria Trousseau says that it first becomes painful, a "colourless fœtid serosity" escapes, and a thick greyish flabby membrane appears on the surface. The edges of the wound are swollen and violet-red in colour. The disease does not usually extend but remains stationary for months. When the *epidermis alone is removed* the raw surface becomes covered with a white membrane and a kind of "erysipelas" soon develops round it. On the surface of the latter the epidermis is elevated in many points by small masses of "lactescent serosity." The vesicles thus formed run together and burst, the exposed dermis being then covered with a white membrane. These new centres join to the main centre and to each other and so the disease spreads. The pellicular concretions gradually become thicker and the most exterior layers become softened, putrid, greyish-black, and fœtid. In one case he saw gangrene attack the part. The invasion generally takes place from the superposed parts towards the dependent parts, this probably being due to the irritation of the serous secretion. He has seen it commence on the hairy scalp and spread to the loins. When the disease extends rapidly the fever may be very acute but it is usually like the hectic fever accompanying suppuration. The patients died after the manner of those suffering from malignant diphtheria. Daviot[5] states that he had most commonly seen cutaneous diphtheria occur *spontaneously*, although Trousseau maintains that it is always preceded by a breach of surface.

The preceding remarks are quite sufficient without any further references to the literature to show that cutaneous diphtheria was a frequent and fatal affection during the epidemics of that period and that it was liable to be very extensive.

In the case under consideration the patient was sent to the Homerton Fever Hospital on Sept. 30th, 1903, by Mr. A. F. Cole, certified to be suffering from diphtheria. Mr. Cole gave the following history of the case: "The patient, a female child, aged one and a half years, was brought to the out-patient department of the Mildmay Mission Hospital, Bethnal Green, E., on Sept. 29th, 1903. The mother stated that there was a 'sore' in the left groin which had been increasing gradually for seven days: that it had come 'by itself,' and even on careful inquiry *no history of any scratch or wound of any kind could be obtained*; her brothers and sisters were quite well. On examination there was a gangrenous patch with sinuous edges and about three by two inches in extent surrounded by an inflammatory areola about half an inch in width. It commenced in the groin where the site of ulceration was occupied by a blackish scab and was apparently spreading upwards mainly on the abdominal wall. This more recent ulceration showed what were evidently sloughing portions of skin of a dirty white colour. There was nothing to be seen approaching the appearance of a membrane and the edges gradually merged into healthy skin, but in the more central portion the loss of substance was considerable. The left labium majus was greatly swollen but no trace of ulceration could be found upon it. No glandular enlargement was observed. The child did not seem to be very ill at this time; dressings saturated with 1 in 4000 biniodide of mercury were applied and she was taken home. On seeing the child again that evening she was admitted to the children's ward. Within one hour of her admission smears and cultures from the surface of the gangrenous patch were taken. The smears revealed typical bacillus diphtheriæ and the same organism was grown in pure culture upon the serum."

Effect of Baths, Massage, and Exercise on T, June 10th, 1899, p. 1652.

Clinique Médicale, tenth edition, book i., p. 472.

[2] Quoted by Bretonneau, First Memoir, New Sydenham Society, 1859, p. 18.

[3] Ibid.

[4] Dictionnaire de Médecine, 1835; Archives Générales de Médecine, 1830, tome xxi., p. 541, and tome xxiii., p. 383.

[5] Relation d'une Épidémie de Diphthéropathie, Gazette Médicale, 1846, p. 178.

The following is a brief *résumé* of the course of the disease obtained from the Fever Hospital notes: "On admission to the Homerton Fever Hospital the lesion was seen to be limited to the left iliac region and upper part of the thigh, extending from the upper limit of that region to a line [illegible] inches below it. [illegible] in outline. There [illegible] and the left labium majus was swollen, red, and tense. There were no vaginal discharge and no fœtor. There were a few scattered ulcers about the size of split-peas in Scarpa's triangle below the general mass of ulceration. The child was pale; pulse regular and of good size and tension; temperature 97° F.; fauces pale and clean. 12,000 units of antitoxin were given and local treatment was applied. Cultures taken from the lesion showed the bacillus of diphtheria growing quite pure. The bacilli were mainly of the long variety. Oct. 1st: The [illegible] t and several times during [illegible] rectum and the vomiting [illegible] set in. The local lesion [illegible] vomiting was profuse and persistent and the urine was loaded with albumin. The wound was clean and granulating. From Oct. 5th to 18th: The child vomited persistently. Oct. 28th: The patient was very pale and losing flesh rapidly. There was no obvious palsy but the child was very limp and helpless. Oct. 30th · Face without expression. Breathing jerky and irregular. No obvious palsy. Knee-jerks not obtainable. On Nov. 1st the following note was made: 'The child is lying in an absolutely helpless state, unable to move its legs which remain in whatever position they are placed. The arms, hands, and fingers can be moved slightly. All the muscles are flaccid and wasted. The knee-jerks cannot be obtained and the superficial reflexes are absent. The child can swallow. The respirations are jerky, with sucking in of the abdomen and [illegible] *is of the* diaphragm. T[illegible] now and then. The wo[illegible] healed.' The child died at 10 P.M. on the same day (the forty-first day of the disease)."

Pathological examination.—A post-mortem examination was performed on the morning after death. The local lesion consisted of a patch of healthy granulation tissue about three-quarters of a square inch in extent and surrounding this was a narrow zone of thin very slightly contracting cicatricial tissue. The scarring [illegible] lesion had been much more [illegible] ance at the beginning had sug[illegible] had left no scars. The body was thin and emaciated. All the vital organs appeared healthy to the naked eye.

Histological report.—The heart was fixed in Muller's fluid and stained by Marchi's method. It showed a small amount of fatty degeneration comparable in extent with that found in a case of diphtheria proving fatal at this stage of the disease. *There were no increase in the connective tissue of* the heart and no intermuscular infiltration. The heart failure in this case was secondary. The amount of degeneration would probably not have given rise to any symptoms of heart failure except as the result of some strain. This is the usual course of events in diphtheria, death from heart failure in the *later* stages of that disease being secondary to a general failure of the nutritive processes, to some complication, or to some strain which the weakened heart is unprepared to meet. Extensive fatty degeneration was present in the liver but in no way to be compared with the almost total degeneration [illegible] which occurs in many fatal cases of late [illegible] the vast majority which were normal. On the whole, each region of the central nervous system examined was regarded as practically normal. The vagi, phrenics, median, intercostal, and anterior crural nerves were examined. All these nerves were normal except the anterior crural and here [illegible] but a small portion of the visible fibre. The changes consisted of cloudy swelling, the fibres being irregular in outline and finely granular in appearance. Many fat globules were seen and in these cases the myelin sheaths were completely broken up. In many fibres the axis cylinders were irregular in outline, in *some places swollen and in others broken across. The* majority of the degenerated fibres were lying singly in the middle of bundles of normal nerve fibres.

As mentioned at the beginning of the paper this case is interesting from the point of view of the rarity of this type of the disease nowadays and important in that it might easily have been undiagnosed except for a prompt bacteriological examination. As far as we are aware this is the first case which has been examined histologically and the findings agree with those which might have been expected to occur in a case of diphtheria proving fatal at a late period of the disease. The results of the pathological examination also afford confirmation of the fact that in the later stages of diphtheria very little fatty degeneration of the heart or degeneration of the cells of the central nervous system *is to be found but that degeneration of the peripheral* nerves is quite likely to be met with, whereas in cases dying from acute diphtheritic toxæmia extensive fatty degeneration of the heart and acute degeneration in certain cells of the central nervous system are the rule. This question has recently been discussed by one of us (C. B.) in THE LANCET[6] and therefore will not be entered into in this paper. Whether this was a case of primary cutaneous diphtheria or a diphtheritic infection of a previous lesion must remain an open question.

TUMOUR OF THE RIGHT CAUDATE NUCLEUS AND FRONTAL LOBE.

By D. McCAY, M.B., B.CH. R.U.I.,
CAPTAIN, I.M.S.; RESIDENT PHYSICIAN, MEDICAL COLLEGE HOSPITAL, CALCUTTA;

AND

E. O. THURSTON, F.R.C.S. ENG.,
CAPTAIN, I.M.S.; RESIDENT SURGEON, MEDICAL COLLEGE HOSPITAL, CALCUTTA.

THE following case of a glio-sarcoma of the caudate nucleus and prefrontal lobe of the right side appears to us to be of sufficient clinical *interest to be put on record, not only* on account of the difficulty of arriving at a definite diagnosis but also on account of the peculiar set of signs and symptoms *exhibited by the patient.* The degree of difficulty in the localisation of tumours of the cerebrum varies with the site, and the difficulty is very much greater if the tumour should be situated in those parts of the brain to which the name of "silent areas" has been applied. The prefrontal lobe has generally been considered to be one of these areas. It has been pointed out by many observers that a lesion of *the frontal lobe does give rise to a fairly* well-defined group of symptoms. In a most interesting and instructive paper in THE LANCET of Feb. 8th, 1902, p. 363, Dr. W. Elder and Mr. A. Miles have recorded a case of tumour of the left prefrontal lobe successfully removed by operation and they have fully discussed the diagnosis and symptoms observed in their case. The perusal of this paper gave great assistance in arriving at an opinion of the true nature of the condition of our patient. The symptoms observed in lesions of the frontal lobe they consider to be produced by "an interference with inhibition, with attention, and with judgment, which are probably the highest functions of the brain, rendering man pre-eminent amongst living creatures."

The patient, a man, aged 35 years, was an engineer [illegible] from England to [illegible] of syphilis, alcohol, or mental troubles. On the arrival of the ship in Calcutta on Feb. 20th, 1904, the patient was admitted to the General Hospital for pain in the right side of the head and *fits of giddiness.* He was found to have some loss of memory, particularly with regard to recent events, and to have lost in a great measure all sense of decency and shame. While in hospital he improved to some extent and left to rejoin his ship, but was taken ill immediately again and was brought to the Medical College Hospital and admitted on April 5th, 1904.

---

[6] THE LANCET, Feb. 4th, 1905, p. 278.

On admission the patient, who was a strong, powerfully built man, was very dull and slept practically all the time. He could be roused easily enough but was very slow in answering questions and evidently could not keep his attention fixed on any one subject for any length of time. On being left alone he immediately went to sleep again. On being questioned as to where he was he always replied "in the General Hospital," although repeatedly informed that he was in the Medical College Hospital. Hearing was normal; there was no aphasia and cerebration appeared to be slow and deliberate. Reading and writing could not be tested, as he refused to oblige us. There was paresis of the lower part of the face on the left side and of the left arm and leg; there were no sensory symptoms. The reflexes were lost; there were no ankle clonus and no trophic disturbance. The patient could only walk a few steps and then by throwing most of the weight of the body on the right side; he was distinctly unsteady in his movements and he showed a great tendency to fall to the right when sitting up in bed or on attempting to walk. He complained of headache all the time, which was limited to the frontal region of the right side. The skull over the right frontal lobe was painful and tender on percussion and appeared to be slightly swollen. There were no real involvement of the sphincters of the rectum and bladder, no vomiting, and no optic neuritis; the bowels were constipated. He still took a marked interest in his food, though listless and apathetic to a marked degree concerning everything else. With regard to the circulatory system the heart was normal and the pulse was slow and regular and of moderate tension; there were no signs of atheroma. The temperature was 98° F. and continued normal till after the operation. The other systems were normal.

As to the progress of the case there was a steady increase in the dulness and apathy and on April 8th he passed urine and fæces in the bed, probably not from any real loss of control of the sphincters but from carelessness regarding the impropriety of doing so. On the 12th his bowels were moved with difficulty and he began to have some trouble in swallowing. By the 19th the lethargy passed into stupor and he could only be awakened with great difficulty; all desire for food also seemed to have gone. The paresis did not become any more marked and there was never any real paralysis. The tenderness and bogginess over the right frontal region increased and he always winced on percussion over it. The chief points on which we had to rely for a diagnosis were headache, giddiness, loss of memory, loss of modesty and sense of decency, slight paresis of the left lower face, arm, and leg, listlessness and apathy, slowness of pulse, with persistent normal temperature, and tenderness over the right frontal region. Speaking generally a picture such as this points to increased intracranial pressure. The diagnosis had to exclude hæmorrhage, embolism and softening, dementia and atrophy of the brain, and abscess.

A. Against hæmorrhage we had: (1) the gradual development of the symptoms; (2) the loss of memory and mental symptoms developing first; and (3) absence of any associated lesions—e.g., albuminuria, high-tension pulse, hypertrophied left heart, atheroma, &c.

B. Against softening due to embolism or thrombosis. Embolism is excluded for the same reasons as hæmorrhage and the absence of any endocarditis or septic condition still further supports its exclusion. Thrombosis may be excluded from the absence of any history of syphilis, starvation, malaria, no general paralysis of motion or sensation, and the age of the patient.

C. Dementia and gradual involution of the nervous system, beginning in the psychical centres, might have explained the case but the history of the case and the short duration of the symptoms were sufficient to exclude dementia.

D. Against abscess we had: (1) no evident source of infection—ear disease, pyæmia, &c.; (2) persistent slowness of the pulse with normal temperature; and (3) no history of injury, &c.

E. In favour of tumour we had: (1) the gradual onset and steady increase in severity of the symptoms, indicating a gradual increase in the intracranial pressure; (2) the persistent headache, slow cerebration, and lethargy; (3) the slowness of the pulse, with normal temperature; and (4) the paresis of the left side of the body. Against this view was the fact that some of the most important signs of tumour of the brain were absent, more particularly vomiting, optic neuritis, and loss of reflexes, in what was considered a lesion of the upper motor segment.

With regard to the locality we had the following localising points: (1) paresis of the left lower face, arm, and leg; (2) the peculiar mental symptoms; (3) headache chiefly confined to the right frontal region; and (4) tenderness and bogginess of the same region. The paresis pointed to an implication of the fibres passing from the Rolandic area to the internal capsule, and as the paresis was very imperfectly developed we considered that the pressure of the tumour backwards was limited. That the cortex was not involved was evidenced by the fact that there were no convulsions, no aura, and no epilepsy. The peculiar mental symptoms—loss of memory, apathy, loss of sense of shame, loss of inhibitory power—we thought to be strong evidence of the lesion being situated in the frontal lobe. All these symptoms are intimately associated with abolition of the functions of the frontal lobe and are largely due to a loss in the power of inhibition of the individual, so that the patient is reduced almost to the condition of an animal deprived of its cerebrum. These points are extremely interesting in our case, as from a perusal of the literature of the subject one would be inclined to consider the left prefrontal region of more importance than the right as far as the above functions are concerned. (At the time we took pains to make sure that the patient was right-handed.) Allan Starr, from a study of the cases recorded of this region, concludes: "The form of mental disturbance in lesions of the frontal lobe does not conform to any type of insanity. It is rather to be described as a loss of self-control and a subsequent change of character. The mind exercises a constant inhibitory influence upon all action, physical and mental, from the simple restraint on the lower reflexes, such as the sphincters, to the highest control over the complex reflexes, such as emotional impulses and their manifestation in speech and expression. This action of control involves judgment and reason—the highest mental qualities. Thus we would expect the partial destruction of the frontal lobes to be accompanied by errors of judgment and reason of a striking character; one of the first manifestations would be a loss of that self-control which is the constant accompaniment of mental action and which would be shown by an inability to fix the attention to follow a continuous train of thought or to conduct intellectual processes. It was this very symptom that was present in one-half of the cases collected. It did not occur in lesions of any other part of the brain."

The absence of vomiting in our case may be due to the fact that the tumour was situated so far forward; as the nearer the tumour is to the vomiting centre in the medulla the greater the tendency to vomit. Our patient was examined for optic neuritis on admission, before the increase in intracranial pressure was marked, which may account for its absence. On the above evidence a definite diagnosis of tumour of the frontal lobe of the right side was made and the patient was transferred to the surgical side with a view to operation. On April 21st Captain Thurston opened the skull over the area of the tenderness; further than an evident increase in the intracranial pressure nothing abnormal appeared on the outer surface of the brain. An incision was made in the cortex and a finger inserted and the brain around was gently and carefully palpated for any mass but nothing was found. Although nothing could be discovered during the operation of the nature of a tumour, the diminution of the intracranial pressure alleviated the more pressing symptoms. Consciousness returned and the patient could answer questions and he made marked use of his arms, wiping his mouth with the sheet after coughing. He still passed urine and fæces in bed. Next day there was a good deal of coughing and expectoration. He tried to undo the bandages. He vomited and the temperature rose to 101·5°. On the 24th he became unconscious; his temperature was 103·2°. He never recovered consciousness and died on the evening of the 26th.

Necropsy.—At the post-mortem examination the following was the condition of the brain. 1. The right ventricle was distended with fluid and dilated anteriorly, bulging forwards into the frontal lobe. 2. The floor of the right ventricle showed a reddish-brown tumour of the corpus striatum, projecting into the cavity of the ventricle and pushing the third ventricle over towards the left. 3. The left ventricle contained excess of cerebro-spinal fluid. Nothing else abnormal was found. The tumour was a glio-sarcoma of the caudate nucleus, rapidly growing and projecting into the frontal lobe, pressing on and infiltrating the bundles of fibres coming from the frontal lobe to the internal capsule. The posterior part of the tumour was pressing on the internal capsule and would thus account for the motor paresis. The greatly increased amount of cerebro spinal fluid with the accompanying increase in intracranial pressure explained the gradually increasing stupor. The several connexions of the frontal lobe with other parts of the brain would assist in explaining the mental condition of our patient. Our reason for recording this case is to add another to the list of lesions of this region already reported, where it has been possible to localise the site of the lesion before death.

TWO CASES OF TETANUS TREATED BY ANTITETANIC SERUM.

BY R. ATKINSON STONEY, M.B., B.CH., B.A.O. DUB.,
VISITING SURGEON TO THE ROYAL CITY OF DUBLIN HOSPITAL.

As the serum treatment of tetanus is still on its trial I think that no apology is needed for the following brief records of two cases which have recently been under my care in the Royal City of Dublin Hospital.

CASE 1.—The patient, a male, aged 34 years, was admitted to hospital on Oct. 31st, 1904, suffering from severe burns of both hands and legs, the result of his bed taking fire from the ashes of his pipe while he was asleep. He was found by his wife unconscious in bed with the bedclothes smouldering. Both hands and wrists were severely burned, three fingers on the right and two fingers on the left hand being completely destroyed. The burns on the lower extremities were less severe and were situated chiefly around the ankles and heels. After admission the temperature [illegible] to 101° on the fourteenth evening but came down the next morning.

On Nov. 16th—that is, the seventeenth day after the accident—the patient complained of some stiffness of his neck. During the day this increased and in the evening there were some stiffness of the jaws and difficulty in opening the mouth fully. He was removed to the observation ward and powders containing 30 grammes of chloral hydrate and one drachm of bromide of potassium were ordered to be given by the rectum every six hours. On Nov. 17th the patient had frequent spasms during the day, chiefly affecting the abdominal muscles and lasting only two or three seconds; he was given a subcutaneous injection of [illegible] the mo[illegible] up, hea[illegible] able to [illegible] P.M. wa[illegible] had very frequent spasms. While under observation he had 31 distinct spasmodic contractions of the abdominal muscles in two minutes; after this chloroform was administered to induce sleep. He slept only at short intervals for about four and a half hours. On the 18th the temperature was 103·4°. He had constant spasms. Ten cubic centimetres of antitetanic serum were injected into the spinal canal by lumbar puncture. The spasms became more severe and the patient died at 1 P.M. [illegible] an hour before [illegible] termination.

[illegible] mitted to hospital on the evening of March 9th, 1905, complaining of stiffness of the jaws and difficulty in swallowing. Three weeks before he got a splinter of wood under the nail of his right middle finger; it was removed at once and on admission the wound was completely healed and [illegible] unday, March 5th, pr[illegible] ident, the patient fir[illegible] ecame worse and pa[illegible] The bowels had not been opened since the previous Monday. He was unable to swallow anything except liquids. On examination [illegible] unable to open [illegible] could only be [illegible] contraction of [illegible] raction of the abdominal muscles were present. There were no stiffness or contraction of the muscles of the extremities and no spasms. The temperature on admission was normal and remained so throughout his stay in hospital.

The patient was ordered a large simple enema which had a very good result. He was ordered powders containing one drachm of bromide of potassium and half a drachm of chloral hydrate by the rectum every six hours. On March 10th he had slept for six and a half hours during the night. He felt better except for the stiffness of the neck which had increased. Ten cubic centimetres of Pasteur's antitetanic serum were injected subcutaneously. He passed a quiet day, he had no spasms, and his neck was less stiff in the evening. In the evening one slight spasm was observed while the patient was half asleep. On the 11th he had slept well during the night and was feeling better though his neck seemed stiffer. Ten cubic centimetres of antitetanic serum were injected. He slept a good deal during the day. On the 12th he had slept all night. His neck was still very stiff. The abdominal muscles were very hard and well-marked opisthotonos was present. Ten cubic centimetres of antitetanic serum were injected. He was better able to open his mouth. On the 13th he had slept well all night. Ten cubic centimetres of antitetanic serum were injected. The patient was given some bread soaked in milk and beef-tea which he swallowed without difficulty. He was feeling much better, though the stiffness of the neck still continued and there was pain in the chest on drawing a deep breath. On the 14th he had slept all night. He had no pain in the chest, his neck was less stiff, and he was able to open his mouth better. The powders were ordered to be given every eight hours. From this time onwards the course of the case was uneventful, though the contraction of the abdominal muscles and the stiffness of the neck disappeared very slowly. On March 24th the powders were stopped and on the 31st the patient was allowed out into the grounds and was discharged on April 7th.

These two cases present a marked contrast to one another. In both the incubation period was long, in the first case 17 days and in the second case probably 18 days. In both the temperature was normal on the first appearance of the symptoms, in the second case it remained normal throughout the course of the disease; but in the first case after a preliminary fall it rose rapidly through 10·2° in 20 hours. In both cases the treatment was the same—i.e., injection of serum and the administration of large doses of bromide of potassium and choral hydrate by the rectum. In the one case death occurred within 60 hours of the onset of the first symptoms whereas the second patient recovered. In the first case the spasms were both frequent and severe, while in the second only one was observed. Case 1 may, I think, be regarded as hyperacute in spite of its long incubation period and Case 2 was certainly chronic. The only conclusion that I can draw from these two cases is that the result was due to the degree of infection and was not materially altered by the treatment.

Dublin.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Bacillus Influenzæ as a Cause of Endocarditis.—Gonococcu Endocarditis.—The Vitality of the Typhoid Bacillus in Shell-fish.

A MEETING of this society was held on April 18th, Dr. E. KLEIN, Vice-President, being in the chair.

Dr. T. J. HORDER read a paper on the Bacillus Influenzæ as a Cause of Endocarditis and dealt with two cases of influenza septicæmia in which the bacillus was cultivated from the blood. The first case was that of a man, aged 31 years, who was admitted to St. Bartholomew's Hospital in May, 1904. Blood cultures were undertaken upon four separate occasions and were positive each time. Some of the cultivations obtained consisted of very large numbers of colonies, as many as 100 per cubic centimetre of blood. The method adopted was to puncture a vein with a sterilised needle attached to a five cubic centimetre glass syringe and to inoculate broth and agar tubes immediately. The morphological and cultural characters of the organism obtained were those of the bacillus influenzæ, as described by Pfeiffer and others. Post-mortem [illegible] the diagnosis which had been arrived [illegible] was a single mass of vegetation [illegible] left auricle which yielded a good growth of the influenza bacillus on cultivation. Sections through the endocardium also showed masses of bacilli. The second case was that of a boy, aged 13 years, who was admitted to the Great Northern Central Hospital in November, 1904. Blood cultures were undertaken twice and each time a good growth of the bacillus influenzæ was obtained. This case also was fatal. The diagnosis was again confirmed by obtaining the organism from a single large vegetation which projected into the mitral orifice. In the first case the diagnosis had been arrived at by blood culture six weeks, and in the second case five weeks, before death. In both cases a marked leucocytosis occurred. Extensive investigations were made into the cultural properties of the organism. The pathogenicity was also tested in several animals but no positive results were obtained. No other organism was demonstrable either in the blood cultures or in the hearts post mortem. Several lantern slides were shown.—Dr. W. BULLOCH said that of late years he had had considerable difficulty in recognising the influenza bacillus, whereas during the epidemic of 1892-93 he had no difficulty in doing so. He thought that the organism shown was stouter than that originally described and figured by Pfeiffer. He congratulated Dr. Horder on the manner in which he had worked out two most difficult cases.

Dr. HORDER reported the first instance of successful cultivation of the gonococcus from the blood in this country. It was accomplished in the case of a man, aged 21 years, who was admitted to St. Bartholomew's Hospital three and a half months after an attack of gonorrhœa. He was at the time of his admission suffering from malignant endocarditis. Blood cultures were made twice which yielded copious growths of the gonococcus both times. The patient died a month after the diagnosis had been established. Post mortem the gonococcus was cultivated from the vegetations upon the mitral valve. Lantern slides of the cultures, films, and sections through the endocardium were shown.

Dr. KLEIN having explained the scope of the inquiry and the methods for determining in a given oyster and other shell-fish at a given period the number of bacillus typhosus as also of bacillus coli communis with which the shell-fish had been supplied, summarised his results thus: 1. Oysters readily took up into their interior the bacillus typhosus which had been introduced into their shell or into the surrounding sea water. 2. Oysters, clean at starting, rapidly cleared themselves of the ingested bacillus typhosus if they were kept in clean sea water which was frequently changed. 3. Oysters, clean at starting, cleared themselves of the ingested bacillus typhosus to a less extent and more slowly if they were kept in a "dry" state—i.e., out of the sea water. 4. Oysters from a polluted locality cleared themselves of the ingested bacillus typhosus to a less extent and at a slower rate, even if kept in clean sea water, than oysters clean at starting. 5. Oysters from a polluted locality retained the ingested bacillus typhosus to a markedly larger extent if kept "dry"—i.e., outside the water. 6. The process of "clearing themselves" of the ingested bacillus typhosus could not be owing to the oyster merely "passing out" the ingested bacillus typhosus but must be due to a large extent to an inherent power of the oyster of *directly devitalising the microbe*. The experiments with the "dry" oysters proved this and it was also evident from the rapid rate at which this microbe disappeared from the oysters kept in clean water if compared with the very small number of the microbe (bacillus typhosus) found at the same time in the surrounding sea water. 7. Oysters which had been infected with the bacillus typhosus and which were then kept in a "dry" state till they had practically cleared themselves of the microbe, when subjected to reinfection with the bacillus typhosus appeared less capable of dealing with this microbe even if they were kept in clean sea water than the reinfected oysters which had always been kept in the water. This could be explained by the obvious supposition that oysters, by being kept for some days out of the water, were not possessed of the same degree of vitality and activity of their tissues as oysters were which had always been kept under normal conditions—i.e., in water. 8. Oysters from a polluted locality and containing a large number of bacillus coli very rapidly cleared themselves of this microbe, both those kept in as also those kept out of the water. This showed that the bacillus coli was foreign to the oyster and was rapidly destroyed by it. 9. However largely infected with the bacillus typhosus the oysters at no time presented to the eye any sign of such infection; they remained in all parts normal in aspect. This was the case not only with the infected oysters kept in sea water but also with the infected oysters kept in the "dry" state. There was only one exception—viz., an oyster derived from a polluted locality, which oyster had been for 11 days out of the water. 10. During the time of these experiments (part of September, October, and part of November) the oysters lived quite well in *sterile* sea water frequently changed. There was no alteration noticeable in the aspect of the fish; they remained plump and juicy and capable of promptly and tightly closing the shell. 11. Cockles readily embodied the bacillus typhosus present in the sea water. While the number of these latter appeared at first to diminish in the body of the cockles it soon increased to a considerable degree, for five days after the cockles had been removed from the infected water and kept in clean sand the number of bacillus typhosus exceeded three times the number initially present. Their subsequent diminution proceeded only slowly since even ten days after removal from the infected water the cockle examined still contained in its body 69,000 bacilli. 12. Mussels also readily embodied the bacillus typhosus—in fact, the analysis seemed to show that mussels did so to an extent greater than oysters or cockles. As regards the fate of the bacillus typhosus in the mussels these appeared to stand between oysters and cockles, since in mussels the bacillus typhosus underwent gradual diminution, but this diminution was incomparably slower than in oysters although it took place somewhat more quickly than in cockles. Direct experiments were made by placing clean oysters—free from bacillus coli—in sea water infected with normal human fæcal matter or with domestic sewage in which the number of bacillus coli communis was ascertained. It was found that while the oysters readily ingested the bacillus coli communis they as readily cleared themselves of this microbe if afterwards placed and kept in clean sea water; from which it followed that just as the bacillus typhosus so also the bacillus coli communis was a microbe alien to the oyster and when present in it must have been derived from the surroundings.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens.—Labour occurring in Synostic Pelvis.—Report of Rotunda Hospital.

A MEETING of this section was held on April 7th, Professor ALFRED J. SMITH, the President, being in the chair.

Dr. H. JELLETT showed a Fallopian Tube with Calcified Nodules filling its lumen, the remains of tuberculous infection.—Dr. R. J. ROWLETTE, Mr. E. H. TWEEDY, Dr. R. D. PUREFOY, Professor E. J. MCWEENEY, and the PRESIDENT took part in the discussion, and Dr. JELLETT replied.

Professor MCWEENEY showed a specimen of Ruptured Tubal Pregnancy with Demonstration of Chorionic Villi which had been removed by Mr. A. J. M. Blayney at the Mater Misericordiæ Hospital from a woman, aged 24 years, who had been suddenly seized with acute abdominal pain and collapse. The abdomen on being opened 24 hours after the onset of symptoms was found to contain much blood. The ruptured tube was discovered and removed, whereupon the patient made an uneventful recovery. The sac was of about the size of a large hazel-nut and lay near the uterine end of the tube which was widely ruptured and contained a mass of blood clot to which some whitish shreds adhered. The fœtus was not seen. Microscopic sections showed the shreddy matter to consist of tufts of chorionic villi, some of which were inclosed in a thin epithelium-covered membrane of doubtful nature. The stroma of the villi exhibited marked metachromatism on staining with Ehrlich's hæmatoxylin. It was covered with a double layer of cubical cells (Langhans' cells) on the outside of which were scattered without any regularity large multi-nucleated masses of protoplasm (syncytia). In the intervillous spaces were groups of large mononuclear cells without intercellular substance (trophoblastic cells). The mass of blood clot contained isolated syncytia in its clefts and also large groups of [illegible] elements lying at a considerable distance [illegible] illi. The syncytial cells [illegible] and were identical in appearance with the multi-nucleated so-called "foreign-body" giant-cells found wherever intrusive matter was undergoing absorption. Professor McWeeney suggested that their function was to cause the natural structures to melt away and thus provide nourishment for the ovum prior to the establishment of vascular connexions with the mother. Their nuclei seemed to be proliferating by gemmation, not by mitosis. The mucosa of the Fallopian tube was intact save at one spot where it was replaced by a fibrinous mass. The delamination of its muscular bundles was apparently being accomplished by swarms of small mononuclear cells resembling lymphocytes. The excellent state of preservation of the structures mentioned was his chief reason for exhibiting the specimen.—Dr. PUREFOY, Dr. JELLETT, and the PRESIDENT spoke and Professor McWEENEY replied.

Dr. JELLETT read notes on a case of Labour occurring in a Unilateral Synostic (Naegele's) Pelvis.—Dr. W. J. SMYLY, Dr. PUREFOY, and Dr. T. G. MOORHEAD spoke and Dr. JELLETT replied.

Mr. TWEEDY read the report of the Rotunda Hospital for the year 1903–04.—The discussion was postponed until the next meeting of the section.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this society was held at the Paddington Infirmary on March 23rd, Mr. C. B. Lockwood, the President, being in the chair.—Dr. Maurice F. Squire, the medical superintendent of the infirmary, showed the following cases: 1. A case of Mitral Stenosis complicated with Complete Paralysis of the Legs terminating in Recovery. The patient was a woman, aged 40 years. On admission she suffered from marked cyanosis and dyspnœa with dilated and hypertrophied heart and presystolic murmur. She appeared to be improving when a fortnight later she was suddenly seized with cramp, loss of power, and numbness in the legs. She was very collapsed, there was incontinence of urine, and knee-jerks were absent, but there was no girdle pain. She recovered from the collapse in a few hours but her legs remained paralysed for about three weeks, when they began to recover gradually and now she was able to walk well. 2. A case of Neuro-retinitis in the Left Eye. The patient was a woman, aged 59 years, who had suffered from rheumatism seven or eight years ago. Her eyes had been weak for two years and one year ago she found that she could not see anything with the left eye. In her right eye there was now a commencing cataract. [illegible] clear but the fundus showe[illegible] white area in the region of [illegible] hypertrophied and there was a double mitral murmur. 3. A case of Myopathic Dystrophy. The patient was a man, aged 37 years, whose mother had been similarly affected. His eyes had always been prominent. He first noticed weakness in his legs ten years ago and it gradually came into his arms also. There was no sensory disturbance. He had been treated by means of electricity, strychnine, and otherwise without benefit. He said that he was able to walk a long distance but could not raise himself from the ground if he happened to fall. The muscles of the face, the shoulder, the upper arm, and the thigh were especially affected. 4. A case of Neuritis due to Lead (wrist-drop). The patient was a man, aged 33 years, and a painter. There was no history of colic. He had been addicted to alcoholic liquor and began to lose power in his hands and feet a few weeks before Christmas, 1904. There was complete paralysis of the extensors of both wrists, the supinator longus was very weak, and all reaction to electricity was lost in the affected muscles. There were no sensory changes. There was a marked blue line on the gums. Under treatment, which consisted in the use of magnesium sulphate and electricity, some power had returned in the extensors of the thumb. 5. A case of Tabes Dorsalis. The patient was a man, aged 54 years, whose illness dated from a severe attack of influenza in 1892. In June, 1895, he was bedridden and unable to walk at all. The symptoms included retention of urine, five or six "lightning pains" per diem, occasional gastric crises, rectal tenesmus, marked incoördination of the legs but not any of the arms, and absence of knee-jerk; the pupils were variable, being sometimes contracted and sometimes unequal but the Argyll Robertson phenomenon was not present. In January, 1897, he could walk a short distance with assistance. At present he walked with two sticks. He had the Argyll-Robertson pupil and primary optic atrophy. There had been no treatment. 6. A case of Friedreich's Disease in a man, aged 38 years. There was no history of either syphilitic infection or hereditary predisposition. The illness commenced ten years ago with trembling of the limbs and difficulty in walking which had gradually increased. At present he was quite unable to stand, there were incoördination of the hands, and irregular swaying movements of the head and the arms. His speech was thick, slurred, and slow; there were nystagmoid movements of the eyes when he turned to one side; knee-jerks were absent but the plantar reflex existed. The reactions of the pupils were normal. There was no sensory disturbance, scoliosis, or pes cavus. 7. A case of Paralysis Agitans in a man, aged 61 years. The first symptom of the disease was tremulousness of the hands which was noticed in April, 1903. At present the patient had a mask like expression of the features and a general "set" appearance of the upper part of the body. 8. A case of Firm Ankylosis of both Hip-joints. The patient was a man, aged 35 years. Both his hip-joints were operated on 18 years ago on account of "diseased bone." A tuberculous abscess near the left trochanter was evacuated in November, 1904.——A meeting was held on April 13th, Mr. C. B. Lockwood, the President, being in the chair.—Dr. Edmund Cautley read a paper on Convulsions in Children. In infancy the main predisposing causes were the incomplete development of the higher nerve centres and the possibility of hereditary influences. Alcoholism was an indirect rather than a direct cause, by leading to bad feeding, unsuitable surroundings, and neglect. Tuberculosis, syphilis, and other nutritional disorders conduced to fits by causing general debility in the child. Out of 300 cases 44 began in the first six months of life, 52 in the second six months, 76 in the second year, 44 in the third year, and 27 in the fourth. After that the age incidence varied little. Rickets was a factor by impairing nutrition and giving rise by its complications to numerous exciting causes. Enormous importance was attributed to dietetic causes and their influence was regarded as partly reflex and partly toxic. The younger the infant the more probable was it that a simple reflex intestinal irritation was present. In almost every case under six months of age the fit could be definitely traced to unsuitable food. In the second six months errors of diet were the main cause but there was often associated rickets, bronchitis, or gastro-enteritis. After the fourth year a few cases could be definitely ascribed to food, such as pork, bacon, peas, and similar indigestible foods. Dentition might be regarded as a mild exciting cause in infants who had had fits or who were strongly predisposed to them. Usually the fits did not cease with the eruption of the teeth and numerous other factors were present. The canine teeth were the ones most frequently to blame. Teething was often associated with fever and resulted in imperfect digestion of food. The fits were due to the intestinal irritation rather than directly to the teething process. Worms were regarded as of comparatively little importance but were an occasional cause by producing irritation or intestinal catarrh. Dr. Cautley then gave an outline of the course of treatment and reminded his hearers that in all cases careful watch must be kept for the development of signs of disease. It must never be forgotten that in the presence of numerous possible causes of a fit the actual exciting cause might be overlooked.—A discussion followed in which Dr. J Taylor, Dr. Sydney P. Phillips, Dr. J. F. H. Broadbent, and Mr E. Laming Evans took part.—Mr. H. S. Clogg then read a paper on Appendicitis in Childhood, in which he remarked on the relative infrequency of appendicitis in children, estimating that about 10 per cent. occurred before 15 years of age.—The paper was discussed by Mr. F. Jaffrey, Mr. Raymond Johnson, Mr. Peyton T. B. Beale, Mr. T. Crisp English, and the President.

HUNTERIAN SOCIETY.—A clinical meeting of this society was held on April 12th at the London Institution, Dr. F. J. Smith, the President, being in the chair.—The President showed a case of Sprue or Hill Diarrhœa in a woman, about 35 years of age, recently returned from India. Th[illegible] and sicknes[illegible] they had [illegible] offensive. [illegible] India there [illegible] were reduced to 20 and in England to six, whilst in hospital single days had passed without a motion; however, the volume of these motions was vast. As soon as vomiting commenced the mouth became blistered and very sore along the edge of the tongue and on the lips and cheeks. Her weight during the nine months of the illness had fallen from 8 stones 12 pounds to 4 stones 6 pounds and the wasting had continued in spite of the amelioration in her symptoms in England.—Sir Patrick Manson agreed provisionally with the diagnosis as the symptoms appeared fairly typical. He pointed out that the characteristic change in sprue was an almost total atrophy or erosion of the mucous membrane from the mouth to the anus. Secondary shrinkage of other organs such as the liver followed. No micro-organism had been certainly identified as the cause of the disease. He was inclined to regard the atrophy rather as the result of exhaustion due to long-continued over-stimulation of the alimentary glands but especially the liver by tropical residence. The prognosis was exceedingly grave and although sprue was not of the same dramatic character as plague and cholera yet with typhoid fever it produced more European deaths in tropical countries. When the destruction of glandular tissue had passed a certain point recovery was impossible. He then reviewed the symptoms which were as in the above recorded case. He laid great stress on the cleanness of the tongue when there was so much alimentary disturbance. The treatment was directed by the idea of exhaustion of the alimentary glands. The food must be the least possible in the smallest quantities and most easily digested. The patient should be placed in bed and kept warm to economise energy. Milk should then be given with a teaspoon or through a straw slowly every two hours and at first during the night. Not more than three pints should be given in the day. Nothing further should be done until increased appetite and solid fæces indicated a commencing convalescence. The milk might then be slowly increased to six pints a day and for at least six weeks nothing more should be given. When milk properly given did not agree the patients did not recover. No drugs were of any use and most were harmful. Raw strawberries, however, had in many cases a most remarkably curative effect. The prognosis was almost hopeless after 50 years of age.—Dr. M. M. Bernstein spoke highly of the extract of bilberry in the treatment of chronic diarrhœas and this could be obtained at all seasons.—Mr. H. L. Barnard referred to a case of long-continued diarrhœa cured by the daily use of preserved raspberries, currants, and blackberries.—Dr. O. K. Williamson showed a case of Chronic Swelling of the Arytenoids. The lungs were healthy and he regarded the case as a very early one of primary tuberculous laryngitis.—Dr. Bernstein showed a man, aged 25 years, with Fibrous Ankylosis of the Left Shoulder Joint of two years' duration. There was no history of trauma and in spite of the rather acute onset he regarded the case as tuberculous. The muscles moving the shoulder joint were wasted. The opinion of the meeting was against wrenching or excision as the movements of the scapula were free and good.—Dr. W. J. M. Ettles showed a case of Aneurysm of the first part of the Right Axillary Artery. The subclavian was not apparently much involved. The patient was a ship's officer and the swelling had been first noticed after he had been pinned between a bull and the side of the ship during heavy weather. Medico-legal questions had arisen as to whether the aneurysm was then produced. Dr. Ettles asked for opinions as to treatment by (1) pressure, (2) electrolysis after introducing gold wire, (3) excision, or (4) proximal ligature.—Mr. Barnard strongly recommended proximal ligature of the subclavian at the outer border of the scalenus anticus. The aneurysm itself was deep and inaccessible; the brachial plexus was in close relation; several arteries originated from this part and probably a fusiform enlargement extended up beneath the clavicle.—Dr. Stanley B. Atkinson showed sections of Bilateral Inguinal Tumours removed by Dr. Wheelton Hind from a woman, aged 37 years. The sections were apparently testicular in structure and Mr. Shattock had supported this opinion. The vagina was imperforate but otherwise the patient was strictly feminine.—Dr. J. Dundas Grant showed a patient suffering from Slight Difficulty in Swallowing for over a year with occasional regurgitation of small quantities of unchanged food several hours after its consumption. There was a small elongated swelling on the right side of the neck, close behind the hyoid bone; when this was compressed a frothy fluid could be seen by the laryngoscope, welling up in the right hyoid fossa. The radiogram taken after the swallowing of bismuth showed a dark patch corresponding to the swelling, which was, therefore, almost certainly a diverticulum of the pharynx.

Manchester Medical Society.—A meeting of this society was held on April 5th.—Dr. J. Dreschfeld showed four members (mother, two sons, and one daughter) of one family affected with Thomsen's Disease. In the mother the affection was only slightly marked; the elder of the two sons, aged 16 years, showed the symptoms well. The muscles of the forearm and hands and the muscles of the leg were chiefly affected and of the facial muscles the orbicularis palpebrarum. The younger brother (aged ten years) and the girl (aged 12 years) showed the same symptoms but in a slighter degree. Dr. Dreschfeld referred to the various groups of cases belonging to this type of disease. Besides the characteristic hereditary form described by Erb, to which most of the published cases belong, there are some cases in which only one member of the family is affected and in which the symptoms come on later in life. A third group of cases has been described by Eulenburg and others in which there is the hereditary element but in which the symptoms only appear during the cold weather and not during the hot season, and a fourth group may be distinguished in which besides the hypertrophy of the muscle and the myotonic reactions there is also noticed muscular atrophy. In many cases of the ordinary and typical Thomsen's disease examination of the muscles has shown besides the hypertrophy of muscular fibres that also some muscle fibres are markedly degenerated.—Mr. F. A. Southam mentioned a case of Pyloric Obstruction due to Fibrous Stenosis, the result of contraction of a cicatrised gastric ulcer, occurring in a male, aged 58 years. Loreta's operation (digital dilatation of the pylorus) had been performed six years previously and for about four years the symptoms were relieved. Obstructive symptoms then began to recur and about 12 months subsequently gastro-enterostomy was performed with a very satisfactory result.—Mr. Alexander Wilson read a paper upon the Treatment of Accidents from Chloroform. He pointed out that the initial symptoms of grave danger were not diminished respiration but acceleration of the respiratory movements due to anæmia of the respiratory centre resulting from failure of the circulation. For treatment he advocated the prompt application of vigorous artificial respiration, which to be successful must be begun before cessation of the respiratory movements. In cases where there is engorgement of the right side of the heart the patient should be temporarily raised into the sitting position.—Dr. W. E. Fothergill endeavoured to afford an explanation of the occurrence of both amenorrhœa and menorrhagia as symptoms of anæmia. While the ancient "plethoric" theory of menstruation had been dropped long ago it had a modern equivalent in the view that menstruation is an expression of the predominating anabolism characteristic of the female organism. On this view an anabolic surplus would exist in the healthy female from puberty to the menopause. During pregnancy this would be expended upon the fœtus, during lactation in milk, and at other times in a periodic menstrual discharge. The time of occurrence of this discharge would appear to be determined by the glandular activity of the corpus luteum. Amenorrhœa could thus be of two kinds—it could be due either to the absence of an anabolic surplus or to the absence of a normal corpus luteum. The amenorrhœa of anæmia was doubtless of the former kind, as the occurrence of pregnancy during anæmic amenorrhœa indicated the continuance of ovulation and corpus luteum formation. The occurrence of menorrhagia during, and secondary to, anæmia (as opposed to the occurrence of anæmia secondary to menorrhagia) was doubtless observed in certain cases. This was best explained by the assumption that in certain circumstances the uterine muscle together with the cardiac and other muscles are so deteriorated in anæmia that their usual control over the vascular supply of the uterine mucosa is lost. In support of this view the causation of various other forms of uterine hæmorrhage was shown to be due to muscular insufficiency.

Society for the Study of Disease in Children.—A meeting of this society was held on April 14th, Mr. R. Clement Lucas being in the chair.—Dr. C. W. Chapman read notes on a case of Hysteria in a girl, aged ten years. At first she suffered from anorexia, excitability, and morbid affection for her parents. Gradually the excitability was replaced by listlessness, so that she hardly answered questions. Subsequently she was seen by two other physicians who diagnosed cerebral tumour. The child became bedridden with complete loss of power and sensation in the legs, emaciation, and incontinence of urine and fæces. At times she declared that she was quite blind. Dreadful screaming fits occurred daily, attracting the attention of passers-by. She was then separated from her friends, put in a hospital, and made a rapid recovery. 20 years had elapsed since without any return of the former symptoms.—Mr. R. C. Dun (Liverpool) described a case of Congenital Deformity of Both Forearms in a boy, aged five months, in a position of complete pronation. A bridge of bone extended downwards and inwards from the neck of the radius to the upper end of the shaft of the ulna. There was absolute fixation but the muscles contracted properly. He had been unable to find any record of a similar condition.—Mr. C. Batchelor (Staines) reported a case of Exophthalmic Goitre in a girl, aged three years, the daughter of healthy parents in a good position of life and without any evident cause. The earliest signs were prominence of the eyes and attacks of passion. Later, there was distinct enlargement of the thyroid and the attacks of passion became more frequent. The heart's action was accelerated. A year after the onset the exophthalmos was very marked; the pulse was between 120 and 140; there were marked carotid pulsation, breathlessness on exertion, and von Graefe's sign, but no tremors. She died from exhaustion after an attack of diarrhœa and uncontrollable vomiting at the age of six years and four months. Admirable photographs of the case were exhibited.—Dr. Edmund Cautley showed a specimen of Verrucose (Infective) Endocarditis of the Aortic Valves and Aorta from a boy, *aged eight years. No other valves were affected. From* the condition of the valves Dr. Cautley thought that there had been a primary congenital lesion and that the terminal infection was of recent origin. The child had been in another hospital some years before for a "weak heart." The left ventricle was hypertrophied but not dilated.—Mr. Dun showed a specimen of Congenital Stricture of the Œsophagus from a boy, aged 31 months, symptoms having begun at the age of 18 months. The obstruction was seven and a half inches from the teeth. The first symptoms were vomiting and wasting. Gastrostomy was performed at the age of 20 months. The child subsequently died from marasmus. The specimen showed a simple stricture an inch above the diaphragm.—Mr. R. H. A. Whitelocke (Oxford) read an interesting paper on Some Points in the Diagnosis and Treatment of Appendicitis in Children.—A long and good discussion took place in which Mr. Lucas, Dr. Percy G. Lewis (Folkestone), Dr. Chapman, Mr. J. P. Lockhart Mummery, and Mr. Dun took part.

West London Medico-Chirurgical Society.—A clinical meeting of this society was held on April 7th, Mr. C. M. Tuke, the President, being in the chair.—Mr. J. Howell Evans showed a Cervical Auricle which he had removed from a child and by the aid of lantern slides explained the origin of these growths.—Dr. Seymour Taylor showed a case of Acromegaly, the subject being a woman, 28 years of age, who had wonderfully improved under treatment with pituitary gland extract.—Dr. A. E. Russell remarked on the tendency in some of these cases of acromegaly for the disease to undergo spontaneous arrest.—The President made a few remarks, as also did Mr. H. W. Chambers and Dr. J. B. Ball.—Dr. Leonard C. T. Dobson exhibited a case of Congenital Ataxia in a boy, aged eight and a half years. The boy was born prematurely and was delivered with forceps. He had been treated during infancy for rickets. He could not talk or attempt to walk until he was four years old. He now walks with a well-marked ataxic gait and has constant choreic movements whilst awake but these movements cease during sleep. His general health is very good and he is a bright, intelligent boy, cleanly in his habits, and has complete control over his sphincters.—Dr. H. P. Potter suggested large doses of arsenic to allay the involuntary choreic movements, with which treatment Dr. E. Arthur Saunders agreed and attributed the condition as probably due to meningeal hæmorrhage at the time of birth. He found considerable benefit derived from administration of hyoscine in increasing doses three times a day.—Dr. G. E. Shuttleworth said that a degree of inhibitory and coördinative power might be gradually developed by judicious muscular exercises, and mentioned an example of a boy under his care at the Royal Albert Asylum, Lancaster, who gradually was taught to use carving tools and eventually became a teacher of wood-carving at the asylum.—Dr. Ball showed a case of Chronic Middle-ear Suppuration with Thrombosis of the Lateral Sinus, in which, in addition to the ordinary mastoid operation, he had laid open the lateral sinus, removed a broken-down clot, and ligatured the internal jugular vein.—Mr. J. G. Pardoe and Mr. E. P. Paton made some remarks on the case to which Dr. Ball replied.—Dr. Saunders brought a case of Congenital Heart Disease before the notice of the meeting, the patient being a girl, aged 15 years. The chief point of interest in the case was the peculiar character of the murmur. This was best heard at the pulmonary base and was of a roaring character, lasting throughout both systole and diastole.—Dr. Taylor remarked how impossible it was to diagnose the exact condition of these cases of congenital heart diseases.—Dr. Saunders also showed a Mongolian Idiot, aged two years and four months.—Mr. Lunn exhibited a case of Tumour of the Tongue in a girl, aged 12 years, which was of doubtful origin.—Mr. Paton considered the case to be an example of lymphangiectasis.—Mr. Lunn also showed a case of Chronic Syphilitic Glossitis.—Dr. Russell showed two cases of Progressive Muscular Atrophy occurring in two cousins. The family history was very interesting, as, although the grandfather and grandfather's brothers were affected, the next generation escaped and the disease appeared in the grandsons.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on April 18th, Mr. C. F. M. Althorp, the President, being in the chair.—Dr. Mitchell read notes on a case of Cutaneous Anthrax treated with [illegible] Recovery. 1[illegible] reviewing t[illegible] discovery of the serum by Professor Sclavo, Dr. Mitchell went on to describe the case, which was eminently suitable for the trial of the serum, the pustule being on the upper eyelid where excision was practically impossible. The chief points Dr. Mitchell wished to emphasise were (1) that no reaction was noticed after the injections; (2) that the swelling and œdema increased rather than decreased; and (3) that sloughing was not prevented. All the tissues down to the car- [illegible] (on the wrist) where the pustule was not excised. Sclavo's serum had apparently no effect and the patient died.—In the discussion which followed the President urged very [illegible] carried out [illegible] d more con- [illegible] r, especially [illegible] should be injected to begin with and repeated in 12 hours. Internal anthrax was not so common now in Bradford as it used to be. [illegible] difficult, there being no [illegible] advanced. The bacilli [illegible] te and were best found [illegible] noted cases of cutaneous anthrax which had recovered without any treatment beyond that of fomenting. Was it not possible therefore that the cases which had recovered with serum treatment might also have recovered without?—Dr. Campbell quoted a case where anthrax bacilli were found in the sputum from a case of bronchiectasis. Recovery was complete. With regard to the number of recoveries reported from Italy after the use of Sclavo's serum Dr. Campbell suggested that the disease occurred there in a milder form than in this country. —Dr. Schofield and Dr. Mitchell replied.—Mr. Horrocks showed an Ovarian Tumour with Torsion of the Pedicle and read a paper on the Advantages and Disadvantages of Some of the Substances commonly used as Sutures in Surgery. The points to be considered in the selection and preparation of a suture were as follows: (1) it must be sterile; (2) it must bear strain without breaking; (3) it must be durable till union takes place; and (4) it must not be the source of mechanical irritation. Mr. Horrocks then briefly reviewed the methods of preparation of catgut, silk, and silkworm gut, and spoke strongly in favour of catgut prepared in xylol after the method employed by Mr. A. W. Mayo Robson.—Dr. Rabagliati said that he had not found the xylol gut trustworthy and preferred it carbolised.—Dr. Wood believed that the material was of very little moment but it must be sterile.—The President, Dr. Mitchell, and Mr. Vaughan Bateson also spoke.—Mr. Horrocks replied.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on April 11th, Sir William J. Collins, the President, being in the chair. A number of medico-legal specimens were exhibited.—The President showed: (1) the Eye of a youth which had been destroyed by the entrance of a large splinter of glass; before completing the operation for removing the globe Sir William Collins had passed his finger round the orbit and discovered a second large splinter of glass which if unnoticed might have led to a fatal issue and a charge of negligence against the surgeon; (2) the Enlarged Thyroid Gland of a man who died suddenly, apparently from asphyxia due to impaction of the thyroid gland behind the manubrium sterni.—Dr. H. Harvey Littlejohn exhibited a series of photographs taken post mortem of persons who met violent deaths, which demonstrated points of medico-legal importance.—Dr. Stanley B. Atkinson (for Dr. Wheelton Hind of Stoke-on-Trent) showed sections of Inguinal Tumours removed from a woman, aged 37 years, which proved her to be a pseudhermaphrodite cryptorchid.—Dr. F. S. Toogood showed the Bones of the Legs and the Brain of a child who died from scurvy rickets in the Lewisham Infirmary. To the layman the appearances would almost warrant a charge of ill-treatment by the attendants had not medical evidence been available.—Mr. Justice Walton then read some learned "Notes upon the Law of Evidence," in which he mentioned particularly the position of the medical witness and points of clinical jurisprudence arising in general practice. He strongly supported the recognition of assessors to aid the court in preference to the employment of medical experts; such assessors, however, would not be allowed in criminal courts, for the Bar would not relinquish the right of cross-examination.—The President suggested that a full discussion of the medico-legal aspects of the Beck case by the society was desirable.—Dr. Blake Odgers, K.C. (recorder of Winchester), discussed learnedly the doctrine of the admission of *res gestæ* as evidence.—Dr. F. J. Smith suggested that to be found concealing weak points in a case was fatal [illegible] success and counsel should be coached by medical men accordingly.—Mr. Troutbeck often found, as a coroner, that it was difficult to limit hearsay and other testimony which, by publication in the press, might prejudice the case; the inquest jury conducted an investigation, not the trial of an issue.—Dr. W. P. Herringham commented upon the vulgar prejudice against "the chicanery of the law" which meant rules of procedure which the public did not understand; these rules were comparable with medical etiquette and both codes were in the interest of the public benefit.—Sir Joseph Walton having replied fully the meeting dissolved.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on April 12th, Professor J. Lorrain Smith being in the chair.—Professor W. St. C. Symmers (Belfast) gave a demonstration on Certain Lesions produced by the Bilharzia Hæmatobia. He commenced by showing a number of lantern slides descriptive of the male and female bilharzia, of the ova, of the miracidium, and of many of the lesions produced by the ova in the human body. An explanation was given of the fact that certain ova possessed a lateral spine while others were terminally spined. Especial attention was drawn to the germinal cells and agglomeration of cells in the miracidium. In many of these points special reference was made to the work of Dr. Looss of Cairo and indebtedness was acknowledged to this distinguished observer for most of the helminthological facts mentioned. Reference was also made to the three known species of bilharzia, Professor Symmers stating that he had recently found a number of worms in the blood of cattle and that possibly these worms were identical with the bilharzia crassa. The modes of entrance into the human body were then discussed with special reference to penetration through the unbroken skin. A description was then given of a large number of preparations which Professor Symmers had brought with him from Egypt, showing the lesions in the bladder, both early and advanced, in the prostate, ureters, bowels, uterine appendages, vagina, liver, and spleen. Numerous examples of bilharzial cirrhosis of the liver were shown and described. Particular attention was called to a dysenteric condition of the large bowel due to bilharzial infection; there were also shown various portions of the intestines in which the serous coat bore enormous fibroid thickenings loaded with bilharzial ova. Finally the relation of bilharziosis of the bladder to cancer was discussed and specimens were shown. The various points of the demonstration were illustrated with microscopic preparations.—Dr. Charles H. Melland showed specimens of Pus from a case of Bilharzia Disease.—Dr. F. Craven Moore (for Dr. D. N. Nabarro, University College, London) showed specimens of Trypanosomata (Human and Animal) from Uganda and East Africa and specimens of the Tsetse Fly (Glossina palpalis).—Professor Lorrain Smith exhibited casts of Leprosy.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on April 18th, Dr. T. Vincent Dickinson, the President, being in the chair.—Mr. John G. Pardoe read a paper entitled "The Choice of Methods for the Radical Cure of Prostatic Enlargements," in the course of which he said that there were certain cases of benign enlargement of the prostate in which the suprapubic method of Freyer could not or should not be used. Mr. Pardoe recognised clinically two varieties of innocent enlargement of the prostate: (1) the adenomatous or pseudo-adenomatous tumours; and (2) the hard fibro-muscular collar-like enlargements. The recognition clinically of these varieties called for a methodical and careful examination of the case: (*a*) by digital examination per rectum; (*b*) by bimanual examination; (*c*) by rectal examination with an instrument in the urethra; and (*d*) by intravesical examination with the cystoscope. Several points were thus ascertained, such as the size of the gland, its consistency, its contour, the mobility or fixity of the gland as a whole, and the appearance presented by its intravesical surface. The adenomatous prostates were soft, elastic, and freely moveable. The fibro-muscular collar-like prostates were firm, slightly elastic, small, and not so mobile. Malignant prostates were hard and fixed. The first should be removed by a suprapubic enucleation. The second should be treated by a perineal prostatotomy. Carcinomatous prostates should be left alone. The reasons for these conclusions were stated at some length and illustrated by a number of specimens showing varieties of prostatic enlargement.—Dr. C. Gould May read notes of three cases of Acholia in children and discussed their nature. He thought the disease was a toxæmia of some kind. He urged the importance of examining the stools in these cases, as otherwise the nature of the illness was very likely to be missed.

Reviews and Notices of Books.

The King's Coroner: Being a Complete Collection of the Statutes relating to the Office, together with a Short History of the Same. By R. HENSLOWE WELLINGTON, M.R.C.S. Eng., L.R.C.P. Lond., of the Middle Temple and South-Eastern Circuit, Barrister-at-Law, Deputy Coroner for the City and Liberty of Westminster and the South-Western Division of London. London: William Clowes and Sons, Limited. 1905. Pp. 292.

THE historical outline of the office of coroner which Mr. Henslowe Wellington has prefixed to a collection of Acts and portions of Acts relating to the subject fills but 33 pages of his volume and is too condensed to do full justice to so interesting a subject. On the other hand, the statutes themselves, long ago repealed, which amplified or defined the numerous and important duties fulfilled by the coroner in the Middle Ages are in themselves dry reading and are not easily to be understood and co-ordinated without explanatory matter by those whose knowledge of early legal history and of early legal language is of a limited character. The compiler's work, therefore, up to the point where statutes now in force are included appears to us hardly likely to commend itself to the general reader, nor does it contain matter to which lawyers are likely to have to refer.

The latter part of the book, which sets out the Coroners Act, 1887, and other Acts of Parliament relating to the holding of inquests, with brief notes giving the names of cases decided in the High Court of Justice, is of a more practically useful character, and coroners and lawyers practising before them should find it a convenient aid in the performance of their duties. We should have thought, however, that as coroners are numerous and as country solicitors and others interested, among whom medical men may be included, are usually not possessed of large legal libraries, the mere citation of the names of cases might well have been supplemented by more or less copious extracts from them upon any points likely to occur in practice. In the course of argument before judges the law reports themselves are part of the necessary equipment of the barrister but in the courts of inquiry held by the coroner and in the references to authority to which he finds it necessary to make such direct recourse the fountain head is not always possible and the coroner, at any rate, may frequently find it useful to have the essential part of a judgment extracted for his use. There would seem to us to be room, therefore, for a carefully compiled work of this class by a sound lawyer, with perhaps chapters not only on such subjects as the law of evidence but a few practical hints on the actual eliciting of it from witnesses and upon such cross-examination as the coroner is justified in administering in order to sift their stories where he has no legal assistance from interested parties. The coroner holds a legal inquiry of a somewhat peculiar character, differing considerably from those conducted by magistrates and by judges and although a medical man with experience as such is undoubtedly the proper person to hold the office, this in itself renders it unlikely that he will have enjoyed a legal practice as well. Perhaps some day Mr. Henslowe Wellington will amplify his work in this direction when he has gained a fuller practical knowledge of the questions which arise.

Turning to a section of the Coroners Act of 1887 of considerable importance to medical men, that, namely, under which they are summoned as witnesses at inquests after being ordered, if such be required, to hold post-mortem examinations, we find that in his present volume Mr. Henslowe Wellington has taken no notice whatever of the practice which prevails in the portion of London where he himself sits as deputy coroner of employing for the holding of post-mortem examinations a gentleman who is not "in actual practice in or near the place where the death" has happened and of retaining the same gentleman in all or in most of the cases which occur as if the institution of a permanently appointed pathologist were intended or sanctioned under the Act. We do not for a moment suggest that Mr. Henslowe Wellington should have entered into a matter of controversy with a view to discussion of it as such but we should have thought that had there been authority to justify the practice in question it would have been worth mentioning, and that as there is a case (R. *v.* Finlay, Irish Reports, 11 Common Law, 498) which seems to bear upon the subject it should have been mentioned. Had the notes included anything in the nature of discussion or explanation, some observations from a strictly legal point of view, or at any rate an extract from the judgment given in Dublin, might have served as a guide to coroners and as instruction to medical practitioners in other districts than that now most affected by the practice alluded to. Still, if we could have wished for greater amplitude either from the point of view of historical study or of legal information, we are far from suggesting that Mr. Henslowe Wellington has done his work badly and we would repeat the wish that some day he, or some other author, may dwell more at length upon the topics on which he has touched. The duties of the coroner have been in a sense curtailed; he is no longer "custos placitorum *coronæ*" and questions of "deodand" do not exercise the juries over whose deliberations he presides. Royal sturgeons may strand themselves on British territory without inquests being required, but if, with the exception of cases of fire within the City of London and of one or two other matters, there is little to demand the coroner's attention beyond the inquiries into the causes and the circumstances of death with which all are familiar under the name of inquests and those preliminary investigations which throw upon the coroner the onus of deciding whether an inquest shall be held, in this respect his labours are so enormously increased and involve such heavy responsibility that his office is of greater public importance than ever. Perhaps in the ideal work upon the coroner's office chapters by a medical practitioner of experience and by an equally experienced advocate, neither of whom need have held office as a coroner himself, might be included with advantage.

Sanitary Law and Practice: a Handbook for Students. By W. ROBERTSON, M.D. Glasg., D.P.H., and CHARLES PORTER, M.D., B.Sc. (Public Health), M.R.C.P. Edin. London: The Sanitary Publishing Company, Limited. 1905. Pp. 756. Price 10*s.* 6*d.* net.

So many books on sanitation in one or another of its aspects have been published within the last few years that it seems a somewhat hazardous task to add to their number, more especially when sanitary law is the subject dealt with. We must confess, in fact, that we opened the volume under notice with some misgivings, mainly owing to the very great difficulty of composing a readable book upon this somewhat unattractive side of preventive medicine. It was, however, easy to recognise before we had turned over many of its pages that we were dealing with a book not only of considerable merit but with one in the arrangement of which much originality and independence of thought had been displayed. The work at once arrests attention and to say this of a book upon sanitary law is to pay it a high compliment. The real merit of the volume is that not only does it combine sanitary practice with sanitary law but that it also introduces into each section pertinent matter which, while educating in law throughout, clothes somewhat dry bones with the flesh of human interest. Moreover, the method adopted of dealing in separate sections with the statutes of the United Kingdom as a whole is a distinct advantage to students and others who wish to ascertain the tendency of modern legislation and to compare certain provisions of the Public Health Act of 1875 with those of later enactments. An extract from the "Contents" will not only make this point clear but will also serve to convey a good idea of the scope of the work. For instance, to take Section XXI. which deals with the water-supply, we find:—

> Water supply, Acts relating to, in England and Wales, Ireland, London, Scotland; Duties of Health Official; Supply of Individual Houses; Shallow Wells; Analysis of Water; Large Schemes for Water-supply; Sources of Water; Hard and Soft Waters, Water Filters.

There are numerous illustrations and diagrams throughout the book and these have the effect of further lightening the forensic difficulties of the volume while materially adding to its interest and information. The book has obviously been written by those who view public health through Scotch spectacles and here and there the refraction of the glasses becomes very apparent. For example, in discussing on p. 25 the duties of the medical officer of health the authors say: "In England, Wales, Ireland and London, the medical officer of health invariably holds the supreme position and to him all the sanitary inspectors are responsible." This certainly should be the case but we are afraid that as it stands the statement is not quite accurate in its application to some of our large towns. We should have been glad, too, had the authors spoken out more fully with regard to the Scotch practice of keeping the offices of the medical officer of health and the sanitary inspector quite separate. Many readers of this book will be also somewhat puzzled to discover that the registration of births, deaths, and marriages is one of the powers and duties of the English Local Government Board but the authors are quite correct technically in attributing these powers to that Board as the Registrar-General addresses his annual reports to the President of the Local Government Board. We should, however, advise the student who may be a candidate for the D.P.H. to amplify this point somewhat, otherwise his examiners might not be sufficiently well up in the inter-relations of State departments to credit him with his knowledge.

On p. 28 the remark is made that "on no account must the M.O.H. visit houses where infectious diseases exist without the previous assent of the visiting medical man." We think that the authors must have intended to refer to *patients* instead of *houses*. Certainly patients should not be thus visited, but it would be contrary to the best interests of public health were the medical officer of health restricted in this fashion in regard to houses when inquiring into the cause of an outbreak of infectious disease. We are sorry, too, that we are not altogether in agreement with the sentiment that "there is little chance of any person obtaining an appointment who does not hold a sanitary inspector's certificate." Unfortunately, in some of the rural districts of England almost anyone who can supervise the highways is regarded as suitable for an inspector of nuisances. On p. 424 has not the Public Health (Water) Act, 1878, fallen into the wrong group? But notwithstanding these criticisms we can recommend the book as one which will prove of value both to the medical officer of health and to the student preparing for a diploma. Both will find, perhaps for the first time, that they can derive interest from the study of sanitary law and if the little defects to which we have referred are remedied and the volume is kept up to date it should certainly occupy a high place in the literature of public health.

The Practice of Obstetrics. By J. CLIFTON EDGAR, Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College. With 1264 illustrations, including five coloured plates and 38 figures printed in colours. Second edition. London: Rebman, Limited. 1904. Pp. 1153. Price 30*s*.

THE fact that only four months had elapsed since the appearance of the first edition of Dr. Clifton Edgar's text-book rendered a complete revision of the work unnecessary. A good deal has, however, been done in the correction of the minor errors which occurred in the first edition and some changes have been made in the arrangement of the various sections. The chapter on the Toxæmia of Pregnancy has been very largely rewritten and added to and the author has grouped under this heading nausea and vomiting of pregnancy, icterus, convulsions, and eclampsia. He believes that the toxæmia of pregnancy will assume even a greater importance in the future than it does at the present time and he defines it as a condition of the blood and metabolism arising from the hepatic insufficiency to which the pregnant woman is liable. Herz's theory of the presence of functional paralysis of the liver in such cases and the work done by Professor J. Ewing upon the same subject are considered in some detail and the author devotes a considerable amount of space both to the trivial and the more serious ailments which he considers owe their origin to this condition. Two new coloured drawings have been added to illustrate this section, one representing the microscopic appearances of the liver in a case of toxæmia of pregnancy and the second showing fatty degeneration and necrosis of the same organ from a case of pernicious vomiting of pregnancy. The author has found it necessary to restate his opinion regarding the indications for the performance of embryotomy and Cæsarean section, which in the first edition were apparently misunderstood. He considers that embryotomy is indicated to-day in but two conditions—first, in all instances where the fœtus is dead and its delivery unmutilated would increase the danger to the mother; secondly, in obstructed labour due to the presence of a monster; and in exceptional cases in which the mother's condition from hæmorrhage, repeated attempts to deliver, sepsis, or shock is such as to render embryotomy a safer means of delivery than abdominal section.

Transactions of the Clinical Society of London. Vol. XXXVII. London: Longmans, Green, and Co. 1904. Pp. 273.

THIS volume consists of 29 communications relating to cases of unusual interest and of brief descriptions of 46 clinical cases exhibited before the society. It is illustrated with 11 plates and there are 15 figures in the text. Many of the communications afford interesting and instructive reading, since they deal with conditions of which the importance has only recently been recognised, and in many such instances the authors have appended bibliographies which cannot fail to be serviceable to other workers in the same field. The first paper, on Erosive Gastric Ulceration with Severe Hæmatemesis, is extremely suggestive and in conjunction with the few cases which have been previously recorded it will probably go far towards modifying current views of the frequency of gastric ulcer as the immediate cause of hæmatemesis. Cases of hæmorrhagic pancreatitis and of myositis fibrosa are also recorded, while the importance attached to examinations of the blood is shown by numerous communications relating to pernicious anæmia, leucocythæmia, and chronic polycythæmia. Congenital narrowness of the pyloric orifice as a cause of chronic gastric disease in the adult is illustrated by notes of seven cases successfully treated by operation. Two examples of pneumococcal peritonitis are described, one in an adult and the other in a child. Most of the plates and figures are clear and serviceable, though in some instances a few references in the text or a short description would have been very welcome. The volume shows that the Clinical Society is worthily maintaining the traditions of the past and that its present work is likely to have an honourable place in the future.

Orthmann's Handbook of Gynæcological Pathology. Translated by C. HUBERT ROBERTS, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond., assisted by MAX. L. TRECHMANN, F.R.C.S. Eng., M.B., C.M. Edin. London: John Bale, Limited. 1904. Pp. 127. Price 5*s*. net.

Orthmann's handbook is such a useful work that Dr. Roberts has been well advised in undertaking a translation of it, more especially as it forms a fitting appendix to his own work on Pathology in which microscopic details, to which this little book is chiefly devoted, are not considered to any great extent. Microscopical diagnosis is of great importance in the treatment of gynæcological cases and it is every day becoming of more importance. As at the present time very few, if any, of the examining boards examine candidates in their knowledge of the minute anatomy of such cases the student does not consider the matter one of much interest, nor is much attention devoted to it in the majority of the text-books dealing with this subject. No such work as the present has hitherto been available for the use of students and we hope now that they have so clear and complete a book at hand that they will devote some of their time to acquiring a knowledge of the histological anatomy of, at any rate, the commoner diseases of women.

The book is divided into two parts: the first deals with the most important and modern methods of technique, which are shortly described, while in the second, or diagnostic, part the author describes the pathology of the female sexual organs. The more uncommon diseases are only briefly dealt with or are altogether omitted, whilst those more frequently met with and which are of especial importance in differential diagnosis are described at length. A short macroscopical sketch in each case precedes the microscopical description. The work of the translators has been carefully and well carried out and the book in its English form is very useful and will no doubt meet with the approval of those for whom it is intended. The illustrations are numerous and well chosen and reproduced.

Transactions of the Association of American Physicians. Nineteenth Session, held at Washington, May, 1904. Philadelphia: Printed for the Association. 1904. Pp. xxiv.-560.

THE prefatory pages show that this association has for its object the advancement of scientific and practical medicine and that an annual meeting is held in the city of Washington for the reading and the discussion of original communications relating to medicine and pathology. From the brief minutes it appears that 22 communications were read and the majority were discussed at three meetings, each of which lasted a little over three hours, while 13 were read by title and are included in this volume. An interesting case of polyuria in typhoid fever was described and led to discussion, while venous thrombosis occurring in the course of typhoid fever formed the subject of a careful analysis of 42 cases which afford a satisfactory basis for some valuable conclusions; this is illustrated by an admirable reproduction of a photograph which, unfortunately, is incorrectly described. The high-tension pulse in nephritis is once more discussed and it is suggested that deficient formation rather than deficient elimination of urea may lead to stimulation of the vaso-constrictor nerves. An analysis of 90 cases of poisoning by illuminating gas shows high and persistent leucocytosis, the infrequency of pneumonia, and the good results of combined venesection and saline infusion. Among other papers of interest may be mentioned the following: Clinical Studies in Arterio-Sclerosis, Diabetes Insipidus, a Case of Prolonged Male Hysteria, Types of Splenic Anæmia or Splenomegaly, and the Relation of Cells with Eosinophile Granulations to Bacterial Infection. The illustrations as a rule are good and clear.

LIBRARY TABLE.

A Manual of Practical Medical Electricity, the Roentgen Rays, Finsen Light, Radium and its Radiations, and High-Frequency Currents. By DAWSON F. D. TURNER, M.D. Edin., &c., Medical Officer in Charge of the Electrical Department of the Royal Infirmary, Edinburgh. Fourth edition. With 200 illustrations. London: Baillière, Tindall, and Cox. 1904. Demy 8vo, pp. xxiii.-435. Price 10*s*. 6*d*. net.—We are glad to welcome a new edition of Dr. Dawson Turner's well-known work. As the title shows, the author has brought his account of the subject well up to date. The great advances which have been made during recent years in the applications of electricity to medical work render the task of dealing with the subject adequately in a single volume a difficult one. The author, however, has succeeded in giving a practical account of the subject which cannot fail to be useful to all students and practitioners who are interested in electro-therapeutics and the new edition forms an excellent introduction to the study of a branch of medicine which is rapidly becoming highly important in many distinct fields of application.

Intemperance. By HENRY HORACE PEREIRA, Bishop of Croydon. London: Longmans, Green, and Co. 1905. Pp. 173. Price 2*s*. 6*d*. net.—A certain degree of uneasiness is inseparable from the perusal of any book upon this subject. This is not due to any fear of disagreement with the author, since the medical profession has abundant opportunities of witnessing the physical and the social results of intemperance, but the disquiet arises from the dread lest the author's conviction should lead him to overstep the limits of discretion. The subject of alcoholism so frequently leads to intemperate language that in a publication like the one before us we instinctively fear that much harm may be done unwittingly by violent denunciations. It is therefore the more satisfactory to be able to state that this new volume of the series of handbooks for the clergy is characterised by restraint rather than by vehemence. The chapter devoted to the medical aspect of intemperance is not marked by much research; the case might easily have been represented in greater detail and in more convincing form. It is needless here to criticise this book at length since it deals largely with social problems that lie outside our sphere. Still it is distinctly likely to be serviceable to all who have opportunities of influencing directly or indirectly the spread or the arrest of intemperance. The chapter on the Causes of Intemperance is written sympathetically, the author giving the first place to two non-preventable causes—our cold, bleak, and changeable climate, and our past history; and he rightly says that it will require generations of patient work to blot out the effect of the evil habits of the past. Of the preventable causes he mentions the housing of the people in our great towns, the temptations offered to them by the number of public houses, the monotony of their mode of life and occupation, and the generally prevailing ignorance as to the nature and properties and danger of alcohol. For its common sense and moderation this book merits very high praise. It is written for the clergy and we hope that those of them to whom this remark may apply, for they are by no means few, will imitate the absence of hysterical heroics when they feel called upon to give public utterance of their views. Sympathy, example, and reason will effect more good than can be attained by emotional denunciations.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. M'KENDRICK, F.R.S. Vol. XXXIX., Part 2. April, 1905. With plates and figures in the text. London: Charles Griffin and Co. Annual subscription for four parts 21*s*., post free.—The articles contained in this number are: 1. The Nature of the Mammalian Diaphragm and Pleural Cavities, by Arthur Keith, M.D. Aberd. The author contrasts the arrangement of these parts in fishes and amphibians, in birds, and in mammals, and shows how in the first of these groups the lungs are altogether contained in the general body cavity, in the second they have become partly extruded, the hinder portion remaining as an air sac, and in the third are altogether external to the body cavity. The diaphragm is a part of the body wall which has been depressed within the body cavity by the extra-abdominal development of the lungs. The analogy between these relations and those of the testis are dwelt upon. A remarkable statement is made, founded on the observations of Dally recorded in our pages (June 27th, 1903, p. 1800) and subversive of a hitherto fundamental doctrine of physiology, to the effect that the curvature of the diaphragm remains practically unaltered during inspiration. The diaphragm is a muscle which compresses the abdominal contents and maintains the portal and hepatic circulation. It arises in the form of dorsal and ventral bands of musculature acting on the roots of the lungs. This article is an important one and is illustrated by many woodcuts. 2. Dissociation in Certain Vital Phenomena, by Anderson G. M'Kendrick, M.B. Glasg., Captain I.M.S. 3. Observations on the Lumbar Arteries, by Alfred H. Young, M.B. Edin., F.R.C.S. Eng., Professor of Anatomy, Victoria University,

Public Health in the Transvaal.

THE immediate and direct results of war are unfortunately disastrous to the public health, war being, in fact, the absolute antithesis of preventive medicine. It seems, indeed, little other than a farce to concern ourselves with what is largely the perpetuation of the unfit at one moment while at another every effort is being made to destroy the flower of two contending nations. Were it possible by means of some international understanding to settle disputes, not otherwise to be arranged, by pitting the unfit of the two opposing nations against one another war from a physical standpoint might prove a powerful and useful instrument for the promotion of the public health! As things stand, the premiss being impossible, the effect of war, as pointed out by MALTHUS many years ago, is to take away from the country the physically, and in large part also the morally, fit and to leave behind the unfit to perpetuate their species. This is, of course, more particularly the case when wars drag on for long periods. But the indirect effects of war may be far otherwise. The awakening of a nation has not infrequently dated from a war which has shown on the one side a nation's strength and on the other a nation's weakness. Then the blessings of peace follow war and the history of preventive medicine begins to be told. When in the future the historian sits down to record the progress of preventive medicine throughout the world the record will consist very largely of an account of the diffusion of English sanitation and ideas through the instrumentality of her Crown and self-governing colonies. Other nations, however, will also justly claim their share. For instance, the story of the battle fought by the Americans in Havana against, not the Spaniards but, the stegomyia fasciata, the bearer of yellow fever, is an excellent example of hygienic progress made immediately after war.

To turn from generalities to the concrete case of the Transvaal we gather from Dr. GEORGE TURNER'S interesting annual report for the year ending June 30th, 1904, what is actually taking place in one of our most recently acquired possessions. Unfortunately, as regards statistics Dr. TURNER finds himself badly circumstanced. He is required to present his annual report at a date when the statistics for the period to which it relates are not available and we trust that his appeal for a better arrangement will be duly heeded. So far as can be ascertained the population of the Transvaal is 1,268,716, this number being made up of 299,327 whites and 969,389 coloured, the death-rate among the whole population for the year under notice having been, according to the figures, only 10 per 1000. But the untrustworthiness of these rates may be gauged from the fact that the recorded death-rate among the coloured population was only 9·5 per 1000, that of the coloured females only reaching 3 per 1000. Obviously, as the writer of the report remarks, there must have been "serious errors in registration." With figures such as these it is impossible to place much reliance upon the statement that the fatality rate of enteric fever among the white patients was 15·9 per cent. while that among the coloured patients was no less than 68·2 per cent. Probably from 25 to 50 per cent. of the cases have not been reported. As regards the etiology of this disease we have heard so much of dust-borne and fly-borne enteric fever in South Africa that it is interesting to find that Dr. TURNER attributes to neither of these factors any material influence in promoting its spread, his scepticism being largely based upon the fact that the prevalence of dust and flies does not coincide with the maximum prevalence of enteric fever. In reference to flies, however, he is causing further observations to be made, and in view of the general acceptance of the theory that these insects are responsible for much diffusion of enteric fever, these observations will be gratefully received.

The figures as regards the fatality rate of dysentery among the white and the coloured patients respectively are as remarkable as those of enteric fever, the rate of the former being 16·3 per cent. and that of the latter being 78·7 per cent. In respect to vaccination we learn that 71,726 tubes of calf lymph were distributed gratuitously during the year, but unfortunately only a very few of the vaccinated returned for inspection. Compulsory vaccination and revaccination are, Dr. TURNER thinks, called for in the Transvaal. The statements concerning the Pretoria Leper Asylum are not very pleasant reading. A considerable proportion of the lepers succeeded in effecting their escape and the compounds had consequently to be fenced in. It has been suggested that the coloured lepers should wear a distinctive dress and that dogs should be employed to track those who escape, but with all our concern for the healthy we cannot read of such a way of enforcing segregation without repugnance. As regards phthisis we are glad to find that the medical officer of health of the borough of Durban, Natal, points out in his current annual report that although pulmonary tuberculosis is communicable it is not so in the same way as is scarlet fever or small-pox and that infection is only possible when certain simple precautions are not observed. We wish that every medical officer of health would point out this distinction, for since the infectivity of pulmonary tuberculosis, up to a certain point, has been realised, the over-anxiety of the public is as marked as the previous carelessness was wont to be.

Dr. TURNER'S report embraces numerous others and that by Mr. C. L. SANSOM, the medical officer of health of Witwatersrand, is of exceptional interest at the present moment. He reports that the most serious disease in this district is pneumonia, more particularly among the natives working underground. Indeed, he attributes to the pneumococcus a death-rate among the native miners of 14·8 per 1000 out of a total death-rate among them of 40·7 per 1000. This peculiar susceptibility to the pneumococcus is attributed by Mr. SANSOM to the defective air space in the compounds and to the windowless rooms into which no sunlight enters. He remarks that "the native working underground for the greater part of the day in vitiated atmosphere, returning at night to sleep in another atmosphere which is not, and cannot be, as pure as it should be, is obviously rendered liable to fall a prey to an organism like the pneumococcus." We are glad, however, to learn that during the past year material improvements have been made, although a death-rate of 40·7 per 1000 among a population of a sex and an age distribution suitable to work in mines requires a good deal of explanation. Mr. SANSOM appeals for some sort of standard in the compound and he points out that although he may effect improvement in one compound the circumstances in the adjoining compound, where administration may not be so intelligent, will remain *in statu quo*. Apparently this remarkably high death-rate is to be attributed in part to the fact that many of the natives are in a poor state of health when they first start working. Scurvy is, Mr. Sansom alleges, rife among them, and it is for this reason that they become an easy prey to the pneumococcus, and he thinks that a greater effort should be made to impart variety to the diet of the miners with a view to diminish the prevailing scorbutic condition. Mr. Sansom seems to us to sum up the situation fairly when he says: "Underground labour can never be classed as a 'healthy trade,' and death-rate and sickness-rate will always be higher amongst underground workers than amongst those employed elsewhere. I am sure more generous diet, elimination of weaklings, and improvements in housing will have a very marked effect in the future, but I am certain that constant surveillance is required and housing, clothing, general care, and especially the character and quality of the food supplied, should be constantly watched by Government officials, because the native mine worker is living here under special conditions sanctioned by Government."

Appeals to Charity.

Exceptional conditions may demand exceptional treatment and yet every method of treatment should be capable of explanation and of justification. By an unfortunate coincidence many of the large hospitals in London are at the present moment making appeals to the charitable public. These appeals are, we have no doubt whatever, in every case fully warranted. It is true that the requisite sums appear to be enormous, but it is also true that new buildings cannot be provided without considerable outlay and that those who contribute desire that all modern improvements should be utilised, and modern improvements as interpreted by the builders of hospitals are very costly. The annual contributions of the charitable show very slight variations, however out of the common the stimuli to generosity may be. Hence, it is evident that when several building funds are started almost simultaneously the chances of success are diminished. The public appeals partake of the nature of competition and business methods are likely to make an undesirable appearance. Happily, it is not generally considered necessary for the members of the staff of the hospitals to be responsible for the collection of the funds to meet current expenses or for the methods employed to attract subscriptions. Every hospital has a board of laymen who have charge of business matters and these boards generally give time and thought to such questions while the medical staff carry on the professional work without being called upon to inquire in any detailed manner into the means adopted to secure subscriptions. But this detachment may be followed by a rude awakening. For example, in the anxiety to capture subscriptions a lay committee might be tempted to resort to methods of advertisement which offend every principle of good taste or to offer commissions upon the receipts which might seriously check the liberality of constant subscribers. The cheerful giver should not be perplexed by thoughts of percentages or by any misgiving as to the way in which his donation may be expended and these things have happened before now when the advertisements of charities have been ill-managed.

Quite recently a series of articles has been appearing in the advertisement columns of the *Times* with a prefatory announcement that these notes "were prepared by a member of the advertising staff" and that "the information supplied has been verified by independent investigation." These notes are marked "copyright," as though they were so valuable that other papers might be tempted to annex them. We have perused with amusement, not unmixed with surprise, these articles which are apparently designed to stimulate popular sympathy in St. Bartholomew's Hospital. Can it really be true that the appalling nonsense contained in these sensational advertisements is necessary in an appeal to the charitable? The headlines of the series are fairly typical. They are the following: "A Great Hospital and its History," "The Hall of Woe," "The Homes of Healing," "The Theatre of Life," and "The Need of St. Bartholomew's." Is there any moral to be drawn from all this parade of the conditions described in such lurid style? We have recently protested against the abuse of literature in the publication of sick room details in the pages of a magazine, but in this series of articles, alternating with displayed advertisements of official character and of equal length, we find graver objections. The appeal to a perplexed public makes much of the truisms of hospital life; it seems to present as marvels of science the conditions which might be met within the walls of all hospitals, and in the end we feel that we have been reading "a thing made of a dream" based upon misunderstood facts. Not for the world would we say anything that would be likely to decrease the chances that St. Bartholomew's Hospital may have of obtaining all the money required by that excellent and venerable institution; but we truly feel that such appeals as have been made in the advertisement columns of the *Times* misrepresent, cheapen, and degrade the services rendered by our great medical charities. The authorities at St. Bartholomew's Hospital may be able to show that in the result much money has been obtained, to which we would reply that the result in this case does not justify the means.

All advertisements must be regarded in the light of business transactions; they are paid for with a definite object. Even accepting the charitable suggestion that this lavish expenditure is paid for and organised by some independent "well wisher" it may well be doubted whether it will not do harm rather than good. Small subscribers will not readily understand the sacrifice of a whale to catch the sprats, even though it is true that a sufficiency of sprats may outweigh a whale. But apart from mere material considerations the policy of permitting such a deluge of hysterical nonsense is open to question, since nothing but ridicule can result from the absurd exaggerations set forth in these articles. To protest too much is to challenge contradiction. To hold up for admiration and commendation facts which are only the details of ordinary routine within the walls of every large general hospital can serve no good purpose. Charitable appeals unfortunately must be addressed as much to the emotions as to the intellect; at least, this appears to be the teaching of experience. While admitting the exceptional needs which are urged in many directions by those responsible for the management of our hospitals, and while cordially wishing that all may succeed in the *endeavour to put their houses in order*, we may express an earnest desire that the unfortunate example set forth in these articles will not be imitated, endorsing the similar wish of our correspondent "A Hospital Surgeon."

Annotations.

"Ne quid nimis."

THE TENURE OF PUBLIC HEALTH APPOINTMENTS.

IN a recent number of THE LANCET two instances were given of the grave results which may follow the very unsatisfactory conditions under which the majority of provincial medical officers of health at present hold office. One referred to Mr. A. Stewart Norman who had been medical officer of health of the Havant rural district for 26 years. The term for which he had been last elected having expired the district council instead of re-electing him as in former years issued an advertisement for a medical officer of health. Happily no other local practitioner applied for the post and Mr. Norman was perforce elected. The other instance has not been concluded so satisfactorily and unless the Local Government Board deals with the matter firmly not only will a grave injustice be done to an eminent public health officer but the public health service will receive one of the severest blows that has been administered to it for a long time. In this case the Chipping Sodbury rural district council sought to sever its connexion with several other councils in Gloucestershire with which it had acted in combination since 1873 for the purpose of appointing a joint medical officer of health. Since the date named Dr. Francis T. Bond has ably served the districts concerned and since 1888 he has been re-elected year by year by the individual councils. In October of last year three parishes were added to the Chipping Sodbury district from Barton Regis, the remaining portion of which district was taken into the city of Bristol. The population of the three parishes was about 4600 and the dispute between the Chipping Sodbury council and its medical officer of health appears to have arisen solely from his refusal to undertake the control of these additional parishes without any additional remuneration. He was eventually given an increased salary at the rate of £33 per annum and apparently out of revenge for his objecting to work for nothing the council has now elected a local practitioner as medical officer of health after first stating in the advertisement relating to the appointment that the officer must reside within the district. Dr. Theodore Thomson, one of the medical inspectors of the Local Government Board, attended the meeting of the district council at which the election took place and stated that the Board disapproved of any secession from the combination of districts and hinted at a possibility of the Board withholding its sanction to the appointment of a local medical man, a course which would prevent the council from obtaining a moiety of his salary from the county council. As already indicated, the council refused to follow the advice of the central authority. The injustice to Dr. Bond is so glaring that it is unnecessary to dwell upon this phase of the question. There is the larger and broader aspect as it affects the public generally which should at once receive the consideration of the Government. The dismissal of an official of the standing and ability of Dr. Bond for no good reason at all and after 32 years of loyal service cannot fail to come as a shock to all provincial medical officers of health and they are not likely to do their work any better with the possibility of similar treatment being meted out to them. Is it likely, too, that the best men amongst medical practitioners will enter the public health service if reasonable security in their official positions is denied to them? There are, indeed, some public health teachers who say that already there is a falling off in the standard of excellence of those who are studying this branch of the profession. The Public Health Bill which Dr. C. F. Hutchinson is desirous of bringing before Parliament has apparently little chance even of being discussed unless the Government affords special facilities, but with the strong recommendation of the Duke of Devonshire's Inter-Departmental Committee on Physical Deterioration to the effect that a medical officer of health who devotes his whole time to the work of his office should in no case, unless convicted of misconduct, be dismissed without the consent of the Local Government Board, there is every justification for the Government bringing in a Bill of its own on the same lines as that of Dr. Hutchinson. Such a Bill ought to meet with approval from both sides of the House, for the principle has been advocated by Mr. Balfour, Sir Michael Hicks Beach, and Sir Francis Sharp Powell, as well as by Sir Walter Foster, Sir Michael Foster, and many of the Members who represent labour interests.

THE TITLE OF THE LICENTIATES OF THE SOCIETY OF APOTHECARIES OF LONDON.

FOR many years it has been felt that the professional title by which Licentiates of the Society of Apothecaries are described is to a certain extent anomalous or incomplete and our columns have on numerous occasions referred to difficulties arising from this cause. The source of the trouble seems to be partly of remote origin but is mainly due to the evolution of new conditions in medical practice during the last 20 years. Briefly stated, the Apothecaries Act of 1815 authorised the Society to appoint a court of examiners, consisting of 12 of its own members, to examine candidates as to their skill and ability in the science and practice of medicine and their fitness to practise as apothecaries. Each successful candidate received a certificate of his being duly qualified to practise as an apothecary and was styled a "Licentiate" of the Society of Apothecaries. The Medical Act of 1858 provided in Section 31 (repealed by the Medical Act of 1886) that every person registered under the said Act should be entitled, according to his qualification or qualifications, to practise medicine or surgery or medicine and surgery as the case might be. By the Apothecaries Act Amendment Act of 1874 the Society was enabled to appoint as examiners persons not members of the Society. The Medical Act of 1886 provided that after June 1st, 1887, no person should be registered under the Medical Acts unless he had passed a qualifying examination in medicine, surgery, and midwifery; this Act further provided that licensing medical bodies might combine for the purpose of holding such qualifying examinations and that assistant examiners might be appointed to take part in the examinations of any licensing body which might be unable to obtain admission to such a combination, the duty of such assistant examiners being to secure the maintenance of the requisite standard of proficiency on the part of the examinees. The Royal College of Physicians of London and the Royal College of Surgeons of England entered into a combination for conducting their qualifying examinations and the Society of Apothecaries being outside this combination requested the General Medical Council to appoint assistant examiners to take part in its examinations. The General Medical Council thereupon appointed at first three and afterwards five Fellows of the Royal College of Surgeons of England to act as assistant examiners in accordance with the provisions of the Act. The diploma of the Society of Apothecaries is therefore indisputable evidence that its holder has passed examinations in, and is entitled to practise, medicine, surgery, and midwifery, but the Society now considers that the holders of its diplomas are placed at some disadvantage as medical attendants of the public owing to the circumstance that their professional title as entered in the Medical Register describes them merely as "Licentiate of the Society of Apothecaries." The Society, in fact, objects to this title and description as being "misleading and containing no indication that they are legally entitled to practise surgery as well as medicine or that they are in fact legally qualified medical practitioners at all." A memorial to the General Medical Council is therefore in preparation praying that the qualification entered, or to be entered, in the Medical Register shall be changed from "Licentiate of the Society of Apothecaries" to "Licentiate in Medicine, Surgery, and Midwifery of the Society of Apothecaries," or some equivalent title.

THE METROPOLITAN ASYLUMS BOARD AND THE TREATMENT OF PULMONARY TUBERCULOSIS.

"BETWEEN 7000 and 8000 persons (of whom the large majority are adults in the prime of life) die every year in London from pulmonary phthisis." Thus runs the opening paragraph of a memorial, presented on April 15th, 1905, to the Metropolitan Asylums Board by a deputation representing sundry associations concerned with the improvement of the public health. The deputation was organised by the metropolitan branch of the Incorporated Society of Medical Officers of Health and received the support of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, the Royal Institute of Public Health, the National Health Society, the Royal Sanitary Institute, and other influential bodies. On behalf of the deputation four speakers—viz., Dr. T. O. Dudfield, Sir William H. Broadbent, Mr. W. G. Bunn, and Sir Edmund Hay Currie—addressed the Board, dwelling upon the gravity of the situation and urging the desirability of action upon the lines already followed in regard to other infectious diseases—e.g., scarlet fever, diphtheria, and small-pox. It was suggested—

[illegible]

The section of the Public Health (London) Act here mentioned is the one which enables the Metropolitan Asylums Board to admit to its fever and small-pox hospitals persons who are not paupers without depriving such persons of any right or privilege or subjecting them to any disability or disqualification. We are given to understand that the deputation was sympathetically received and that the Board referred the matter to its general purposes committee, which, we may note, consists of all the members of the Board, for consideration and report. It goes without saying that we also are entirely in sympathy with the views expressed in the memorial as to the importance of the issue raised by the prevalence of consumption. We wonder, however, whether the deputation fully realised the magnitude of the responsibility which it desired the Metropolitan Asylums Board to undertake. At present the Board has about 40 institutions for the reception of patients of various classes and on Dec. 31st, 1903, these contained 10,812 persons. In the absence of notification it is impossible to estimate with any satisfactory degree of accuracy the number of persons in London who are suffering from consumption, but during the year 1904 there were 7738 deaths from this form of tuberculosis alone. It seems therefore reasonable to suppose that if the provision of adequate sanatorium accommodation devolves upon the Board the work of that body will be at least doubled. The memorial states that "the money value to the community of the lives lost every year from this preventable and curable disease (i.e., phthisis) is enormous and immensely transcends any possible cost to the rates by sanatorium provision." This opinion must, we think, be accepted with some reserve. It involves assumptions as to the merits of sanatorium treatment which are as yet hardly justifiable. As bearing upon this aspect of the subject we would direct attention to an annotation which, under the title "The Value of Sanatoriums," appeared in THE LANCET of Sept. 26th, 1903, p. 896, and to an address by Dr. J. E. Nevins of Liverpool, reported in our issue of April 22nd, p. 1096. The Metropolitan Asylums Board would not, at present, be warranted in incurring a huge expenditure on hospitals for consumptive cases but there can be no objection to its obtaining powers which would enable it to make such experiments in the way of supplying facilities for the open-air treatment of pulmonary tuberculosis as would place the community in a position to decide upon the economic advantages of the procedure.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE election of Sir Richard Douglas Powell as President of the Royal College of Physicians of London will be received with general satisfaction by the medical profession. His invariable courtesy, dignity of manner, and sound judgment render him admirably suited to act as the titular head of the profession and to represent the College both within and without its walls. We offer him our sincere congratulations on his election. At the present time there is an earnest movement on foot to bring about an amalgamation of the principal London medical societies. Sir Richard Douglas Powell is taking a leading part in this endeavour and as President of the Royal Medical and Chirurgical Society he is one of the committee appointed to consider the first steps which will be necessary to bring about the desired result. His election to the Presidency of the Royal College of Physicians of London comes, therefore, at an opportune moment as lending additional weight to his position on that committee. He will thus be a member of the committee in two capacities, for the Presidents of the two Royal Colleges were requested to serve when that body was appointed. The outcome of the proceedings will be awaited with interest.

APPENDICITIS IN A CHILD, AGED 14 MONTHS, DUE TO IMPACTION OF A PIN.

IN the *New York Medical Journal* of March 11th Dr. L. W. Glazebrook has reported the following remarkable case. A child, aged 14 months, an inmate of an orphan asylum, whilst playing at 10 A.M. was noticed to be ill by her nurse. She was cyanotic and had a severe rigor. She was taken up from the floor and cried with pain on being moved. Ten drops of whisky-and-water were given and she fell asleep but was pale and breathed rapidly. She was put to bed and remained quiet until 12 o'clock, when she awoke crying with pain, which appeared to be situated in the lower part of the chest on the right side. The pallor and rapid breathing continued. At 1 P.M., when she was first seen by Dr. Glazebrook, she was semi-comatose and exhibited symptoms of pneumonia. Before she could be examined she died. Her father died some six months previously from some acute disease and she was admitted to the orphanage two months before her death and then appeared to be healthy. At times she had attacks of "wind colic" which yielded to simple remedies. Dr. Glazebrook, who is a physician to the asylum, was never asked to see her previously. At the necropsy the large omentum was found adherent to the middle of the vermiform appendix. The adhesion was very firm and appeared to be of several months' duration. Three-eighths of an inch from the tip a small round mass was felt in the appendix. Upon opening the latter this was found to be the head of a black mourning-pin. At the place of adhesion was a small perforation of the appendix from which about a drachm of green pus was escaping. The point of the pin was in the position of the perforation. No attendant in the orphanage wore mourning-pins. This fact and the density of the adhesion of the appendix to the mesentery led to the conclusion that the child prior to admission, whilst being suckled by her mother, swallowed the pin. The latter punctured the appendix, set up local peritonitis, terminating in the formation of the adhesion. The fatal illness was of only three and a half hours' duration and was due to perforation of the appendix into the peritoneal cavity. Cases of appendicitis due to foreign bodies, for which at one time fæcal concretions were mistaken, are much rarer than was supposed. In 1000 necropsies Dr. Glazebrook found foreign bodies in the appendix only twice.

LIFE INSURANCE OF MEDICAL MEN BY RUSSIAN LOCAL GOVERNMENT.

THE Minsk local government, in view of the threatened invasion of cholera, has invited medical practitioners, irrespectively of creed, to occupy the vacant practices in the province of the Minsk government. In event of cholera appearing in the government the medical men's lives will be insured by the authorities for £800 and those of the students (students of five years' standing are included in the invitation) for £500. This would seem to be a practical solution of a great difficulty. In times of foidemic, of however dangerous a nature, no medical man ural distres to do his duty, but it is impossible for a maeveral other co wife and chöucestershire with which wedad acted in com poverty, since 1873 for the purpose of appointing a joint mn to a officer of health. Since the date named Dr. Francis are Bond has ably served the districts concerned and since 18trt he has been re-elected year by year by the individual councils. In October of last year three parishes were added to the Chipping Sodbury district from Barton Regis, the remaining portion of which ved ised it was taken into the city of Bristol. The population of the three parishes was about 4600 and the dispute between the Chipping Sodbury council and its medical officer of health appears to have arisen solely from his refusal to undertake the control of these additional parishes without any additional remuneraticere He was eventually given an increased salary at e of rate of £33 per annum and apparently out of reve erto for his objecting to work for nothing the council rugs now elected a local practitioner as medical officer the health after first stating in the advertisement relaiism, to the appointment that the officer must reside wmally the district. Dr. Theodore Thomson, one of the mecyllin inspectors of the Local Government Board, attendeeds, so isn ting of the district council at which the elout to untry lace and stated that the Board disapproved cariably e suppo from the combination of districts and inished surely the ity of the Board withholding its sanction ns lost ny medical of a local medical man, a course whiclly bile- crimipating ouncil from obtaining a moiety of hir slowly insure ty council. As already indicated, the c semi- ow the advice of the central authority. y-like d is so glaring that it is unnecessar has

been given and in which constipation frequently alternates with diarrhœa. The palatinoids were given every second hour if necessary, but rarely more than eight a day were required, and soon two or three sufficed. The best time to administer them was found to be after food. The tenderness so frequently noted over the lower part of the abdomen disappeared under this treatment, likewise the distension, but flatulence still proved a troublesome symptom to relieve. There was a steady increase in weight with ability to endure cold and to take exercise without fatigue. Dr. Hartigan maintains that the great advantage of giving cyllin is that it enables the patient to resume an ordinary, though restricted, diet much sooner than when treatment by diet alone is adopted. The drug must not be suddenly discontinued but it should be continued in reduced doses for about a month after all symptoms of disease have disappeared. Cases of sprue are not often seen in this country and consequently few opportunities arise for taking any particular line of treatment. Doubtless, however, cyllin will be tried in eastern countries, China more particularly, where this disease accounts for a large number of deaths, and the results of its administration will be watched with interest.

THE MANCHESTER EDUCATION COMMITTEE AND FEEBLE-MINDED CHILDREN.

THE first special school for feeble-minded children in Manchester was opened by the education committee in April, 1902. Now there are three such schools, affording accommodation as follows. Embden-street school can take 90 children, Hague-street 80, and the Harpurhey Hall school 48, making a total of 218. The second annual report of these schools has just been issued by Dr. Henry Ashby and it states that during the year 1904 there were 159 children amined for admission, of whom 139 were passed and 20 any re rejected. Of the 20 who were rejected eight ... imbeciles and therefore not eligible, while nine were considered as not defective. Dr. Ashby reports that among the upper grade children—i.e., some 30 or 40 per cent. of the scholars—the improvement has been very gratifying and that there is every reason to believe that in the future they will be able to earn their own living at some handicraft. In the next grade, which numbers from 40 to 50 per cent. of the scholars, the improvement is not so marked and it is doubtful whether they will ever be able to earn their own living, but in a labour colony they could contribute materially to their own support. As for the third grade, who number 10 or 12 per cent. of the scholars, it "would be better for themselves and everyone else for them to be inmates of a State-aided institution." The chief causes of the mental deficiency are the fecklessness of parents, bad home conditions, and hereditary influences. As for diet, improper feeding plays a larger part than actual lack of food. On the whole the report shows that the schools are doing much good.

THE PATHOLOGY AND BACTERIOLOGY OF ACUTE MENINGITIS.

OUR knowledge of the pathology and bacteriology of cerebro-spinal meningitis is so recent that a survey of the facts which have been discovered is opportune. Such is furnished by a paper contributed to the *Albany Medical Annals* for March by Dr. W. T. Councilman. All cases of meningitis are cerebro-spinal and strictly speaking the term meningo-encephalitis is applicable, for careful examination always shows some extension of the inflammation to the brain itself. Infectious agents gain access to the meninges by the blood or the lymphatics or by extension from adjacent regions. All forms of meningitis agree more or less anatomically, though there are certain minor differences.

The same kind of exudation may be produced by the diplococcus meningitidis, the pneumococcus, the streptococcus, or the tubercle bacillus. Acute meningitis may be produced by a number of organisms. The three most usually concerned are the diplococcus intracellularis meningitidis, the pneumococcus, and the streptococcus. The first is the cause of the form known as epidemic cerebro-spinal meningitis, which we have recently discussed in THE LANCET of April 14th, p. 1010. But this disease may exist in a sporadic as well as an epidemic form. The mortality is less in this form than in the others and appears to be less in sporadic cases than in epidemics. The diplococcus has been found in the nose associated with acute rhinitis. Possibly it spreads thence to the brain by the lymphatics. With rare exceptions cases of primary meningitis are due to this organism. Out of 61 necropsies performed at the Massachusetts General Hospital and the Boston City Hospital in cases of meningitis 21 were found to be of the epidemic form. In 18 cases the disease was due to the pneumococcus. In six cases the meningitis was secondary to otitis media and in one to infection of a tumour of the sphenoid bone. In one case it was streptococcic and secondary to fracture of the skull; in one, to prostatic abscess; in one, to acute infection of the ethmoid bone; in two, to croupous pneumonia; in four, to broncho-pneumonia and pleurisy; and in two, to acute pneumococcic endocarditis. In but few of the cases did the meningitis appear to be embolic; in most of them it was due to extension by continuity or by the lymphatics. There were 18 streptococcic cases and one was primary. Of the 17 others seven were secondary to fracture of, or operation on, the skull; eight to otitis media or mastoiditis; one to acute streptococcic endocarditis; and one to broncho-pneumonia and cystitis. Fatal sporadic cases were equally divided between the three organisms mentioned above. Two cases were due to the staphylococcus aureus. In one case the anthrax bacillus produced the meningitis, which was secondary to a primary lesion on the face.

THE MORTALITY FROM PLAGUE IN INDIA.

IN THE LANCET of March 25th, p. 807, we commented upon the appalling mortality from plague, a disease which is at present scourging India, and gave it as our opinion that the urgency of the situation has not as yet been fully recognised. At the Comitia of the Royal College of Physicians of London held on April 17th the following motion was proposed by Dr. Norman Moore, seconded by Sir Dyce Duckworth, and supported by Dr. J. F. Payne—

> That in view of the constantly increasing [illegible]
>
> Government on the subject.

The motion was carried and the nomination of the members of the committee was left in the hands of the President. It is true that the prevention of plague in an oriental country presents great difficulties. The poorer classes of India have but little reserve of strength, caste prejudice and religious difficulties stand in the way of such hygienic measures as notification, preventive inoculation, and proper sanitation, while the unfortunate infection of a batch of plague serum with the germs of tetanus which occurred but recently has naturally caused a dislike to this method of prevention. Moreover, the tendency of the oriental races when afflicted by illness is not merely to take no measures for treatment but also to refrain from making any mental effort to get well. This they would consider impious and it is not so very long ago since we in this country viewed cholera in the same way as a divine punishment, so that many persons considered that to take hygienic measures was fighting against God. We have now learned better and have come to agree with the opinion of Salvian concerning the conquest of Rome by the Goths, that our evils are due to our vices. It is not nowadays a characteristic of the inhabitants of these islands to sit with folded hands and not to do their utmost to combat difficulties. We trust that the committee to be appointed will strongly recommend the Royal College of Physicians of London to make urgent representations to the Government and to assist our rulers in every possible way to do their utmost to remove what we must stigmatise as a blot upon our administration of the chief part of our eastern empire.

RESULT OF RECENT RAILWAY ACCIDENTS IN THE UNITED STATES.

A REPORT of the railway accidents in the United States during the months of October to December, 1904, has been compiled and published by the *Inter-State Commerce* Commission. During that period 53 passengers and 189 employés were killed and 1430 passengers and 1868 employés were injured—a total of 242 persons killed and 3298 injured in railway accidents. Other accidents to passengers and employés, not the result of collisions or derailments, bring the total number of casualties up to 14,978—951 killed and 14,027 injured.

HERPES OF THE FIFTH NERVE AND SPINAL LYMPHOCYTOSIS IN MUMPS.

A NUMBER of nervous complications, such as neuritis, meningitis, and deafness, may occur in mumps. The recent practice of lumbar puncture has enabled French observers to throw light on the pathology of these complications. M. Monod has shown that the systematic practice of lumbar puncture in children suffering from mumps frequently reveals the existence of spinal lymphocytosis. M. A. Chauffard and M. L. Boidin have confirmed this fact and have demonstrated a relation between the meningeal reaction and certain nervous symptoms, such as headache and bradycardia.[1] They thought that the meningitic process was localised in the neighbourhood of the medulla and the pons. Subsequently M. Dopter observed facial paralysis in a case of mumps with meningeal lymphocytosis and concluded that it was due to a meningeal lesion in the neighbourhood of the pons. At the meeting of the Société Médicale des Hôpitaux of Paris on Feb. 17th M. J. A. Sicard reported a case which confirms this conclusion as to the localisation of the meningeal process and in which occurred a complication which does not appear to have been previously described in mumps, herpes of the fifth nerve. A boy, aged 12 years, went to hospital suffering from mumps on both sides. The disease began four days previously with fever, insomnia, and headache. On the following day the parotid glands were swollen. He was prostrate and could scarcely walk. He complained of frontal and occipital headache and pains were provoked in the parotid glands by palpation and mastication. The left parotid gland was more swollen than the right. The temperature was 100·9°F., the pulse was 64, and the respirations were 20. Kernig's sign was present in slight degree. The patient was asked to go into hospital but refused. Nine days later he returned with an eruption on the face which had appeared on the previous day and was accompanied with an exacerbation of the headache, the fever, and the general lassitude, although the parotid swellings had almost disappeared. The eruption was a well-marked herpes of the right side of the face situated in the supra-orbital region, on the upper lid, and in the pinna. In the evening he vomited thrice, the neck was rigid, and Kernig's sign was present. The temperature was 101° and the pulse was 70. On the following day fresh vesicles appeared and the left half of the face became œdematous. Lumbar puncture yielded fluid very rich in lymphocytes but limpid. On the following days he rapidly improved and the vesicles dried up. A second lumbar puncture, performed 17 days after the first, showed slight lymphocytosis. The herpes involved the supra-orbital branch of the ophthalmic division of the fifth nerve and the auriculo-temporal branch of the inferior maxillary division. M. Sicard thinks that it was due to extension of the meningeal process to the Gasserian ganglion.

---

[1] THE LANCET, May 7th, 1904, p. 1297.

PRESCRIBING v. DISPENSING IN MEDICAL PRACTICE.

IN May of last year a committee was appointed by the Islington Medical Society to inquire into the relative merits of prescribing and dispensing in medical practice. The points discussed were:—1. The ethical aspects of this question as regards patient, druggist, and practitioner. 2. Objections urged against prescribing on the ground of loss of income by medical men: (*a*) by their seeing patients less often than when dispensing; (*b*) by misuse of prescriptions—e.g., unauthorised repetition and transfer of prescriptions to others; and (*c*) by patients being driven, on account of cost of medicines, to hospitals, dispensaries, and prescribing druggists. 3. Profit or loss on drugs, surgery expenses, and repetitions of medicines under either system. 4. Position of druggists in relation to this subject as regards charges, counter-prescribing, and so on. 5. Position of the poor generally and of club patients under either system. The committee has made its report and the conclusions arrived at by it are the following. As to Question 1 the committee is agreed that, considered from the ethical standpoint, the use of prescriptions is preferable to dispensing. As to Question 2 it states that it would prefer to prescribe but must admit that to do so would entail loss to the practitioner, which loss, however, might by arrangement be minimised. In this connexion it wishes to direct attention to the recommendations of the medico-political committee of the British Medical Association,[1] that—

(*a*) Members of the profession should adopt the practice of indicating on every prescription the period or the number of times for which it was intended to be dispensed.

(*b*) That, in order to prevent copying, all prescriptions should be signed by the practitioner with his full name and address and not merely initialled.

(*c*) That medical practitioners should observe the rule of not recommending drugs or special preparations to their patients by name, but always ordering them by prescription.

As to Question 3, the committee considers that in respect of the items under this heading it is more profitable to dispense than to prescribe. As to Question 4, it believes that druggists are, as a rule, disposed to be amenable to the views of medical men if the latter should agree to prescribe instead of dispensing. As to Question 5, it considers that the prescribing system, if adopted generally, would be applicable to practice among the poor, including club patients.

THE STERILISATION OF CATGUT.

M. Albert Petit in the *Journal de Pharmacie et de Chemie* of March 16th gives the results of his work on the various methods of sterilising catgut. Maceration of the gut in carbolised oil was found to be impracticable because the process takes one year for complete sterilisation and the product is slippery to the touch. Dipping in a solution of nitrate of silver until the gut was blackened and the method of sterilising in a dry heat at 150° C. both gave a hard gut which was difficult to tie. Acetone was not found better for the purpose than absolute alcohol and was rejected owing to its unpleasant odour. The English method of dipping the gut first in formaldehyde and then in boiling water for a time depending on the thickness of the gut is, in the opinion of M. Petit, too complicated a process to be above reproach. He has found the absolute alcohol method to be the surest and the most practical. The actual sterilisation is first effected by gradually heating the gut to 130° C. for half an hour. It is then quite free from water and as a result somewhat brittle, but just before use it is placed in sterilised water or in any antiseptic solution, when it takes up water and regains its suppleness, elasticity, and firmness and may be depended upon as a perfectly sterile suture.

THE ALIMENTARY VALUE OF SUGAR IN TUBERCULOSIS.

IN a contribution to the Société de Thérapeutique René Layfer discusses the value of sugar in the dietary of tuberculous patients. Sugar being easy to take and to assimilate and having a high calorific value might, it was thought, replace a part of the albuminoids in the diet without lowering the weight of the patient. Two cases were taken in which the diet consisted of 300 grammes of raw meat and two grammes of total albumin per kilogramme. The meat was reduced to 150 grammes, equivalent to 1·2 grammes of albumin per kilogramme. At the end of 12 days of this fare increase of weight had ceased in one case and a loss in weight of 300 grammes had occurred in the other. Each patient was then supplied with 70 grammes of sugar in addition and a gain in weight was experienced. In a general way tuberculous patients tolerate for a long time from 50 to 90 grammes of sugar daily. Thus a gain in weight of from 20 to 90 grammes per day was obtained by simply adding to the patient's ordinary diet from six to ten pieces of sugar daily, administered in a little milk after each meal. But sugar was found to be particularly valuable as an addition to a strict milk diet, yielding quite a perceptible increase in weight, as shown by a typical case. A patient who through a loathing of food was taking only from two to two and a half litres of milk a day and had become quite emaciated regained his usual weight in 45 days by adding to the milk diet 200 grammes of sugar daily. It is particularly with milk that large quantities of sugar are tolerated, either dissolved in the milk or dissolved in water and taken after each dose of milk. The writer mentions six other cases in which the diet consisted of three litres of milk a day and from 50 to 200 grammes of sugar; in each case a gain in weight varying from 15 to 75 grammes a day was experienced and the diet was tolerated by the patient.

TUBERCULOSIS IN PENAL INSTITUTIONS OF THE UNITED STATES.

Dr. J. B. Ransom, physician to Clinton prison, Dannemora, New York State, has prepared a report on the above subject for the Eighth International Prison Congress, 1905. The report shows that pulmonary tuberculosis is very prevalent in prisons but that owing to a lack of statistics authentic information on the subject is difficult to procure. Dr. Ransom found it necessary to an intelligent plan of procedure to place himself in touch with all the penal institutions of the country, asking for certain information with regard to pulmonary tuberculosis. With the information thus gained, together with his own experience, Dr. Ransom has summarised the means which he considers most likely to secure the best results in the direction of prevention and treatment of consumption in prisons. Among these are the following: improved construction, housing and working environment, larger, better ventilated and lighted prison cells; the recognition of the prisoner's receptivity to infection and his assignment to the most favourable opportunities for resisting the disease; substitution in so far as is possible of other forms of punishment for those of the solitary and dark cell with starvation diet; provisions for proper clothing, its cleansing and disinfection, and the administration of spray baths and physical exercise in the open air; the absolute separation from the prison population proper of all tuberculous subjects, together with strict regulation of the spitting habit, the destruction of sputa, the absolute disinfection of beds and bedding used by one inmate and transferred to another's use, and the control of the production of dust in living quarters and workshops; special wards for the treatment of all active cases; and a compulsory law compelling the examination of everyone admitted to any penal institution for the purpose of an early detection of the disease. Dr. Ransom points out that it is not only incumbent upon the State to care for prisoners properly upon humanitarian grounds but that it is necessary in the interests of public health to send forth a released prisoner in a good physical condition. For instance, if an individual is sent into the world of free men suffering from consumption in an advanced stage he is both a menace and an expense to the community at large. Therefore, from an economic and public health standpoint, the prisoner's health should be carefully guarded whilst under restraint.

[1] Supplement to the Brit. Med. Jour., Nov. 26th, 1904.

THE VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

WE are informed that the British ambassador in Paris, Sir Francis Bertie, has accepted an invitation to be present at a banquet to be given on May 13th to the British medical men visiting Paris. The honorary secretaries of the London committee ask us to state that the failure of so many members of the British party to respond to the inquiries in the circular addressed to them ten days ago is causing great embarrassment not only to them but also to those who so generously propose to entertain parties at Vichy and Evian and at the watering places of Béarn. We are also asked to state for the information of members of the party that ladies are invited to attend the opening reception at the Sorbonne on Wednesday evening, May 10th, at 9 P.M., and that the return tickets at reduced fares, to be obtained on presentation of a voucher, will be available by any of the S E. & C.R. Co.'s services from Charing Cross or Victoria, will be issued on any date from May 6th to 11th inclusive, and will be available for a fortnight from the day of issue.

THE medical officer of health of the Cape Colony states that for the week ending April 1st the condition of the colony as regards plague was as follows. At East London five cases of plague were discovered during the week, four of the patients being European males and one a native male. Plague-infected rodents were found at Port Elizabeth and at East London, and at the latter place one plague-infected cat was found also. In the other districts of the colony no case of plague in man or in other animal was found. In Brisbane for the week ending March 4th one case of plague was notified, the patient, a man, dying on March 2nd. In the week ending March 11th two cases occurred. One patient was a Chinese, who died on the 7th, and the other a boy whose case was notified on the 9th. For the week ending March 18th no cases were notified. Plague-infected rodents continued to be found.

THE colleagues, former pupils, and other friends of Professor Samuel Pozzi of Paris have arranged to present him with a medal in commemoration of his having presided over the seventeenth French congress of surgery and having been promoted to the rank of Commander of the Legion of Honour. The secretary of the committee in charge of the arrangements is Dr. Jayle. The subscription list will remain open until June 15th and contributions will be received by M. Pierre Masson, éditeur, 120, Boulevard St. Germain, Paris. Subscribers of 25 francs and upwards will receive a bronze medal before the end of the present year.

THE annual dinner of the Royal Sanitary Institute will be held in the Prince's Restaurant on Friday, May 12th, at 7 P.M., the Duke of Northumberland, President of the Institute, being in the chair. All applications for tickets should be made to Mr. E. White Wallis, secretary, at 72, Margaret-street, London, W.

THE Ingleby lectures of the University of Birmingham for 1905 will be delivered on Thursdays, May 4th and 11th, at 4 o'clock, in the Medical Lecture Theatre, by Dr. James Kerr, medical officer (education), London County Council, who has taken for his subject "Mentally Defective Children."

THE death is announced on April 20th, at the age of 72 years, of Sir John Sibbald, M.D., F.R.C.P. Edin., who was from 1878 to 1899 a Commissioner in Lunacy for Scotland and wrote much as a recognised authority upon insanity regarded chiefly from its sociological side.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER IX.[1]

THE COLONIAL MEDICAL SERVICE.

The Colonial Appointments.—Their Anomalies and Contradictions.—The Well-organised West African Medical Staff.

THE duties and responsibilities of the Colonial Medical Service are rapidly increasing with the vastness of the epidemiological fields open to its members. But the service is in a muddle. It contains good berths and often has thoroughly good men to fill them, but it is in course of evolution and presents the inequalities and anomalies arising from its transitional state. The great self-governing colonies, of course, stand in no need of an Imperial service. Canada, Australia and New Zealand, Cape Colony and Natal possess properly equipped medical schools and hospitals. They, notably the first three, turn out sufficient medical men from the local supply to meet the local wants, while they attract by the freedom of colonial life and the opportunities of private practice a certain number of medical men from the mother country. India is manned by the Indian Medical Service, as well as by highly educated and competent natives, to whom some superior opportunities, though not many, are now allowed for holding appointments. These countries represent the flower of our dependencies and they have reached a stage of development when they require no medical service supplied to them from a central government. At the other end of the scale we have countries which are not yet ripe for a civilian medical service and for whose needs, as far as the men of our own race are concerned, the officers of the Army Medical Service, or the medical men in the pay of pioneering expeditions, must suffice. Certain protectorates again, as Cyprus and British Borneo, fall under the jurisdiction of the Foreign Office, with whom the responsibility of finding the necessary medical men will rest until the country becomes a Crown Colony. Until this month Uganda has been in the same position, but on April 1st the jurisdiction over the East Africa Protectorate passed from the Foreign Office to the Colonial

---

[1] Chapters I., II., III., IV., V., VI., VII., and VIII. were published in THE LANCET of Feb. 18th (p. 447), and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), and 22nd (p. 1089), 1905, respectively.

Office. Between these two extremes come the countries the medical departments of which are regulated from the Colonial Office; they are:—British Guiana, Jamaica, Trinidad, Tobago, Windward Islands, Leeward Islands, British Honduras, Fiji, Ceylon, Straits Settlements, Federated Malay States, Hong-Kong, Mauritius, Seychelles, Gibraltar, St. Helena, Falkland Islands, Gambia, Sierra Leone, the Gold Coast, Lagos, Southern Nigeria, and Northern Nigeria. It is in the West Indies and the West African colonies that medical officers are chiefly required and the last six of the countries enumerated have been formed into the West African Medical Staff, a definite and properly organised service which can be considered by itself. In the other colonies special conditions attach to the service, the leading features of which may be mentioned.

The majority of the West Indian appointments involve medical charge of a district, including, as a rule, the care of a hospital, poorhouse, asylum, or other institution and free attendance on the aged and children. Passage money is granted to medical officers on first appointment, an annual vacation on full pay is given not exceeding three months in two years, and there are pensions, as a rule, where private practice is not permitted.

British Guiana.—There are 42 appointments. After two years' probation at a salary of £200 per annum, when quarters are provided but private practice is not allowed, the officer is appointed to the permanent staff with a salary of £400 per annum, rising by annual increments to £700. He can carry on private practice and receives a travelling allowance varying with the range of the duties from £100 to £150 per annum. The governor of the colony can also make appointments to the service of local practitioners who act as supernumeraries upon temporary agreements.

Jamaica.—There are 54 appointments, mainly district appointments with private practice allowed. The salary paid by Government varies from £100 to £250 per annum, and in most cases is £200. Newcomers may be attached temporarily to the public hospital in Kingston, on a salary of £200 per annum, private practice not being allowed.

Trinidad.—In Trinidad there are 32 appointments. After two years' probation at a salary of £250 per annum, with furnished quarters, during which time they are usually attached to the Government hospital, the surgeons obtain district appointments, to which they are promoted as vacancies occur. The pay is £300 per annum, which is increased to £400 and upwards by various allowances for horse, house, or other purposes. These posts carry the right to private practice. After every five years an officer is given an additional personal allowance at the rate of £50 per annum. In future there will be few appointments in Trinidad, as the Government is aiming at the introduction of a system by which the work shall be performed by private practitioners under temporary contracts. In these three colonies there is a Civil Service Widows' and Orphans' Fund established by law, to which all medical officers must contribute 4 per cent. of their salaries.

Tobago.—In the island of Tobago there are three district appointments with salaries of £250 per annum, with quarters.

Windward Islands (Grenada, St. Lucia, St. Vincent).—The 22 appointments are, with few exceptions, district appointments with the right to private practice attached. The salaries paid by Government vary from £250 to £400, with allowances in certain cases.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The 25 appointments are of the same nature as in the Windward Islands. The Secretary of State reserves the power to transfer a medical officer from one island to another in each case. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also allowed private practice.

British Honduras.—There are four medical appointments, besides the principal post of colonial surgeon, in all of which private practice is allowed if it does not interfere with the public duties of the officer. The pay varies from £150 to £250. Two of the medical officers are also district commissioners and receive £300 for the combined posts of medical officer and district commissioner.

Fiji.—The medical service has recently been reorganised and officers appointed in future will be styled Government medical officers and receive a salary of £300, rising by annual increments of £10 to £400. They will be allowed private practice so far as is consistent with the proper discharge of their duty and will have charge of hospitals or of districts at the discretion of the authorities. The posts will be pensionable but an allowance in lieu of free quarters will not be pensionable. There will be ultimately 15 Government medical officers in addition to a senior medical officer (who at present receives £450 and £50 allowance for house rent) and a chief medical officer who will have £600 a year. Government medical officers will be given free quarters or an allowance in lieu thereof. This privilege is non-pensionable.

Ceylon.—The pay of the 36 sub-assistant colonial surgeons and eight other subordinate medical officers is at the rate of from Rs.900 to Rs.1600 per annum. There are nine deputy assistant colonial surgeons, with salaries at the rate of from Rs.1500 to Rs.2500. The 23 assistant colonial surgeons are paid at the rate of from Rs.3000 to Rs.5000 per annum and the six colonial surgeons and three other superior medical officers at a rate of from Rs.5500 to Rs.8000 per annum. The principal civil medical officer receives Rs.15,000, rising by annual increments of Rs.500 to Rs.18,000 per annum. As might be inferred from the scale of payment private practice is allowed to the subordinate officers but the colonial surgeons may take only consultation practice. The medical service of Ceylon is mainly recruited from among gentlemen born in the island but possessing British diplomas.

Straits Settlements.—Two house surgeons in the General Hospital, Singapore, and one in the General Hospital, Penang, receive £300, rising to £360, with free quarters. There are ten other subordinate posts in the medical department with salaries varying from £300 (rising to £360) to £780 (rising to £900). Some of these posts have free quarters attached and the holders of some are allowed private practice within limits. The salary of the principal civil medical officer is £1000.

Federated Malay States.—There are 18 district surgeons on salaries varying from £480 (rising to £540) to £720 (rising to £840). There are two assistants in the Institute for Medical Research on salaries of from £360 to £420. These posts are non-pensionable and the holders are eligible for appointment as district surgeons. Medical officers have no claim to private practice, which is limited, and the enjoyment of it is strictly subject to the permission of the Government.

Hong-Kong.—The principal civil medical officer receives £800 per annum, rising to £1000. There are two health officers of the port, four medical officers of health, and four assistant surgeons with salaries of £480 rising to £720. Most of these appointments are pensionable. Private practice is not allowed and free quarters are only given in a few cases.

Mauritius.—There are 24 medical appointments in all. Of these 14 are minor appointments, with salaries varying from Rs.500 to Rs.1500 per annum. The other 10 appointments have salaries varying from Rs.2000 to Rs.9000. Free quarters are not given in most cases and private practice is not allowed in the best appointments. The service is mainly recruited from among gentlemen born on the island. Officers in the service of Mauritius are required annually to contribute 2 per cent of their salaries towards their pensions

Seychelles —There are four medical appointments The Government medical officer receives Rs 4000 The assistant Government medical officers receive Rs 3000 The holders of these latter appointments have free quarters Private practice is allowed

Gibraltar —There is a surgeon to the Colonial Hospital receiving £275 and an assistant surgeon receiving £96, in each case with quarters, fuel and light allowance, and permission for private practice The surgeon of the hospital, as medical officer of the civil prison and lunatic asylum, receives £55 and horse allowance of £42 The assistant surgeon is also public vaccinator, police surgeon, for which he is paid £45, and port surgeon, for which he receives £109

St Helena —The colonial surgeon receives £300 per annum and £30 horse allowance Private practice is allowed

Falkland Islands —There are two appointments one of which is paid at the rate of £300 per annum, with £25 as health officer, and the other at the rate of £200 per annum Private practice is allowed in both cases

Cyprus —There is a chief medical officer paid at the rate of £500 per annum, two district medical officers paid at the rate of £250 per annum, and one paid at the rate of £200, rising by £10 a year to £250, all enjoying private practice and receiving 2*s* per diem forage allowance These are the only medical appointments in the island which are open to English candidates and they are made by the Foreign Office

All applicants for medical employment in these 18 colonies must be between the ages of 23 and 30 years and must be qualified for registration Preference will be given to those who have held appointments as house physicians and house surgeons, certificates of moral character and of sobriety will be required, and every officer before being appointed will be medically examined by one of the consulting physicians of the Colonial Office There are pension funds established for widows and orphans in Ceylon, Straits Settlements, the Federated Malay State, Hong-Kong, and Mauritius to which all permanent Government servants must subscribe 4 per cent of their salaries

Cape Colony and Natal are, as has been said, self supporting colonies, but other districts in South Africa need the help of the central Government Medical appointments in the Bechuanaland Protectorate and Basutoland are made only on the recommendation of the High Commissioner of South Africa, who usually appoints local candidates Appointments of medical officers to the South African Constabulary are also made by the High Commissioner on the recommendation of the Inspector General Medical appointments in the Transvaal and Orange River Colony are only made on the recommendation of the governor of those colonies

The anomalies and contradictions implied in these notes upon the Colonial Medical Service hardly require to be pointed out. Salaries differ with no apparent difference in work or responsibility In some places there is a widows and orphans' fund, in others there is not, and where it exists the deducted percentages are not uniform Here private practice is allowed and here it is not or at any rate specific permission is omitted In some places the service is largely recruited from the native born, who are given the better berths and in others they do not seem to be taken into consideration There are no settled rules about pensions, allowances, or extra fees Titles are given at haphazard, one man is called a principal civil medical officer and another a chief medical officer It might be guessed that they hold the same rank but a Government medical officer, a colonial surgeon, and a district surgeon are not obviously interchangeable characters There are no provisions for promotion which entail that the headship of the medical department in a colony will be obtained by a member of the medical staff of the colony, so that men may be suddenly disappointed in their hopes of securing berths which had seemed well within their grasp When it is remembered that some appointments are made by the Foreign Office, some by the Colonial Office, some by colonial governors, and others by trading companies it will be seen that it is no overstatement to allude to the service as "in a muddle'

We now come to that branch of the colonial medical service which is a properly organised entity

The West African Medical Staff —The medical services of the West African colonies and protectorates—viz, Gambia, Sierra Leone, the Gold Coast, Lagos, Southern Nigeria, and Northern Nigeria—form one service under this name All the medical officers for the service are selected by the Secretary of State for the Colonies They are engaged in the first instance for one year on probation and, except the principal medical officers are allowed to engage in private practice as long as it does not interfere with the efficient discharge of their official duties There are fair allowances when junior officers discharge the work of their seniors by deputy Stores are transported free out of pocket expenses in travelling are recoverable, there are proper horse, field, and outfit allowances and all medical men are paid 10*s* per diem extra with free rations, or 3*s* in lieu of rations while serving on military expeditions Candidates for the West African Medical Service must be British subjects of European parentage preferably unmarried and between the ages of 25 and 35 years They may choose their colony or protectorate, and as far as possible their wishes will be met, but they must make up their minds carefully as transfers are seldom made

The grades and salaries of medical officers are shown in the following table —

Grades	Gold Coast Southern Nigeria Northern Nigeria			Sierra Leone Lagos			Gambia		
	Minimum Salary	Annual increment	Maximum salary	Minimum salary	Annual increment	Maximum salary	Minimum salary	Annual increment	Maximum salary
	£	£	£	£	£	£	£	£	£
Principal medical officer	1000	50	1200	800	50	1000	—	—	—
Deputy principal medical officer	700	25	800	—	—	—	—	—	—
Senior medical officers	600	20	700	600	20	700	500	20	600
Medical officers	400	20	500	400	20	500	400	20	500

Every candidate selected for appointment will unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months at the London School of Tropical Medicine or at the Liverpool School of Tropical Medicine If for any reason he does not undergo the course before appointment he will be required to take out instruction on less favourable pecuniary terms during his first leave of absence The cost of the tuition, fees board and residence during such instruction, amounting to a maximum of £48 8*s* 10*d* for three months, will be borne by the Government, and a daily allowance of 5*s* will be paid to each candidate during the course and may be *continued* subsequently up to the date of embarkation These payments will be made subject to the candidate signing an agreement by which he will be bound to refund them (1) if he declines to accept an appointment in any of the colonies or protectorates for which he may be selected, (2) if he fails to obtain the certificate referred to in the next paragraph, or (3) if he relinquishes the West

African service for any other reason than mental or physical infirmity or is removed for misconduct within three years of the date of his arrival in West Africa. Every candidate sent to either of the schools of tropical medicine is required to obtain a certificate showing that he has satisfied the school authorities with regard to his regularity of attendance, progress, and proficiency.

The arrangements for special allowances and leave of absence are fair. The ordinary term of residential service is one year, followed by leave with full pay during the voyages to and from England and for four or two months clear in England, according as the officer is returning for further service in West Africa or not. If an officer is detained beyond the year additional leave is given with full pay for ten days in respect of each completed month beyond 12, whether he is returning or not. If he is invalided before the end of the year the leave with full pay is for the voyages and for ten or five days in respect of each completed month, according as he is returning or not. Leave granted on the understanding that an officer will return is known as "return leave" and any pay drawn in respect of such leave is liable to be refunded if an officer does not return. Leave may be extended for a limited period with half or no pay on the ground of ill health or without pay on other grounds. Free passages are given to all officers who are granted leave and on first appointment. On attaining the age of 50 years, or after 18 years' service (of which at least 12 must have been residential), an officer is qualified for a pension calculated at one-fortieth of the last annual salary for each year of service. If invalided after a minimum of seven years' service he is qualified for a pension calculated at the same rate. If invalided before completing seven years' service he is qualified for a gratuity not exceeding three-fourths of a month's salary for each six months of service, provided that he has been confirmed in his appointment and that he is specially recommended by the governor or high commissioner for such gratuity. At the end of nine years (of which not less than six must have been residential) an officer of the West African Medical Staff is permitted to retire with a gratuity of £1000, or at the end of 12 years (of which not less than eight must have been residential) with a gratuity of £1250, such gratuities being *in lieu of* pension.

The successful organisation of the West African Medical Service makes it a practical question to ask why the Colonial Medical Service of the empire should not be organised on similar lines. The colonial service, as a whole, has grown up gradually and has developed with the growth of the empire into a conglomeration of elements that require rearrangement. It should be placed on a basis similar to that of the Army and Indian Medical Services, though avoiding the blemishes in these schemes. The age of the candidates should be made uniform and probably it would be advantageous to admit no one over 28 years of age. There must be hesitation in recommending that entrance should be by a competitive examination, because the multiplicity of examinations is already the bane of the young medical man's life, but an examination in hygiene and tropical medicine should be strict, compulsory, and competitive to this extent that future appointments should in some measure be made to depend upon how a candidate has acquitted himself at this test. All gradation of rank and title should be definitely settled; pay and allowances should be equalised in accordance with such a scheme and in accordance also with the marked unhealthiness of certain districts. The whole service should be a definite department of the Colonial Office; the position of the Foreign Office in having certain appointments to give away in the Colonial Medical Service forms a ridiculous and unnecessary complication, while the powers at present given to colonial governors are as often as not used wrongly. It may be asked: Who knows local conditions better than the local man? The answer to this is that special men should certainly be appointed in special circumstances by the colonial governor. But if the Colonial Medical Service is to be organised into strength the privilege of the governors should be sparingly used. For the filling up of good berths by local men must have a bad effect on the service as a whole because it militates against recruiting in the mother country. Save in peculiar circumstances and with permission of the Colonial Office it would be advisable for all appointments to be filled by the promotion of men in the service. And when outsiders are given berths the appointments should be temporary and supernumerary, although they should be well paid; indeed, they should be exceptionally well paid because they should only be made in exceptional circumstances.

(*To be continued.*)

THE ROYAL ACADEMY.

THE 137th exhibition of the Royal Academy will open its doors to the public on Monday, May 1st. We doubt if that public will consider the exhibition to be marked by any very striking picture—indeed, the want of imagination displayed by the majority of the painters both in subject and treatment is notable, but the collection as a whole is up to the usual standard. The accidents of hanging prevent many of the pictures from showing their merits, but they must always occur at this exhibition. One of the most interesting works in the galleries is Mr. Sargent's portrait (51) of Señor Manuel Garcia, which it will be remembered was painted for presentation and was formally handed over to Señor Garcia on the occasion of the hundredth anniversary of his birth on March 17th. The portrait is in every way worthy both of the artist and of his subject and the many medical subscribers to the testimonial will be glad to see for themselves that it is so. Of Mr. Sargent's other works the most striking is (168) the portrait of the Countess of Warwick. On first sight the right arm appears too short, judged by the standard of the apparent length of the figure, but the eye is led far below the feet of the figure, owing to the train flowing down from the step on which the subject is standing. But when once the position is mastered the apparent deformity disappears. Of other portraits (151) Mrs. Rodocanachi, by Mr. S. Melton Fisher, should on no account be missed, and the same may be said of the other work by this artist, (266) "The Prelude," with its delicate colour scheme of pinks and greys. Besides these we may mention (722) "Portrait of a Child," by Mr. R. Peacock; (789) "A Portrait," by Mr. Frank Daniell, a clever study in blacks; (787) "The Chinese Kilim," by Mr. George Henry; and (176) "Blue-bow," by Mr. J. J. Shannon. In the watercolour room is a very graceful portrait, possibly a pastel, of Miss Fairfax by Mr. St. George Hare.

Of subject pictures one of the best in our opinion in the exhibition is (194) "The Morning of Sedgemoor" by Mr. Edgar Bundy. The artist shows us the rough, untrained, heroic peasants of the West who laid down their lives in a mistaken and premature effort to rid the country of its lawful king. How they failed is known to all but some two years later the last of the Stuarts himself fled. The scene is a barn in which lie asleep, or only just awake, the men who a few hours later were yielding their lives besides the Bussex Rhine, their only arms a few scythes or bills rudely fastened to poles. In Gallery IV. are two imaginative works, one by Mr. J. C. Dollman (236), entitled "Harvest." The subject is not a cheerful one, for it is a long train of wounded men wearily plodding their way, some in wagons and some on foot, along an English country road. In (242) "Midsummer's Eve" Mr. J. H. Lorimer has painted a charming old-world garden in which around a rose-bush swings a dance of graceful unearthly figures. Mr. W. T. Wood in (273) has chosen a place with a most unromantic name, "Pigshoot *Ford*," but he has made a very charming landscape in which nymphs, who, let us hope, did not know the name of the place, are bathing and in (279) Mr. E. Matthew Hale has a powerful work in which barbarian invaders, presumably Huns or Picts, are returning from a fray, driving with them stolen cattle, through a snowy pass.

Of [illegible] ed by the Moon, [illegible] a torpedo destroy [illegible] has her search-lights in full work. We must confess to having been puzzled by the title, for if it is the destroyer which has been betrayed we should have said that there was no need of the moon to betray her for her funnels are spouting flame, but perhaps she has just turned on her forced [illegible] to escape. Mr. Mouat Lou [illegible] shows us a garden with high [illegible] and Mr. J. Farquharson (431) for once has a picture without sheep in snow. In (466) "The Kite," Mr. Charles Sims once more gives us the same breezy effect as in his "Top of the Hill" which was exhibited two or three years ago and (546) "Winter in the Marshes," by the late George Boughton, is a sad reminder of what art has lost by his death. Other notable pictures are (674) "The Shepherd," by Mr. Edward Stott; (711) "Sisters," by Mr. Chevallier Tayler, which is very far from being what is generally expressed by such a name in a catalogue; and (833) "The Doctor," by Mr. Charles E. Stewart. Mr. La Thangue has his usual delightful sun-flecked country scenes and in [illegible] e are many excellent works, [illegible] me near Amalfi," by Mr. [illegible] King," by Mr. A. Rackham; [illegible] " by Mr. G. Murray; (899) "A Surrey Chalk Pit," by Sir E. Poynter; and (937) "A Hanging Committee," a clever study of bats, by Miss Laura Darcy. In the Sculpture Room we noted a striking medallion of Sir William Church, by Miss Ethel A. O. Bower (1793). In the Black-and-White Room there is a novelty in the shape of two coloured prints by Miss E. Milner—namely (1341) and (1347)—being after portraits by Lely and Romney respectively.

GERMAN METHODS OF COMBATING TUBERCULOSIS.

AT the beginning of the year 1904 there were in full activity in Germany 71 public sanatoriums for tuberculous patients (with 15 in course of construction), 27 institutions under private management, about 60 children's homes and hospitals, 27 institutions for the reception of convalescents during the daytime, 26 polyclinics, two rural colonies for discharged patients, and eight refuges for incurables, making an aggregate of 236 institutions all engaged in combating tuberculosis in one way or another. The Red Cross Association and the Patriotic Women's Association have especially distinguished themselves by the energy and zeal with which they have taken up this work. The Red Cross Association alone has established half a dozen sanatoriums in different parts of the empire and also works in the homes of the people, advising and helping where necessary. Agencies giving advice and information with respect to the prevention of tuberculosis are numerous in Germany. At Mannheim in Baden there is a committee having a paid lady secretary who spends two hours each day in receiving the questions of sick people or their friends and these questions after being taken down on special forms are answered by medical men. The committee also employs a nursing sister to visit the homes of the tuberculous poor. To such homes bedding and other necessaries are supplied in case of need and food, such as milk, eggs, and meat, is also distributed. On this committee there are representatives of all the women's [illegible] in the town and it has [illegible] y both the municipality of [illegible] r excellent organisation of [illegible] Information, Advice, and Help for Sufferers from Lung Diseases" which has been established at Charlott[illegible] near Berlin by the Patriotic [illegible] wise making systematic endeavours to cope with the disease. Berlin, Dresden, Munich, Leipsic, Aix-la-Chapelle, and some other large towns have established sanatoriums and isolation homes, whilst other municipalities have provided existing hospitals with special departments for the treatment of tuberculous patients. In Coblentz, Essen, Duisburg, Mülheim, Ruhrort, and Rees a special district tax is levied for the support of sanatoriums for tuberculosis. Where the ground has already been efficiently covered by philanthropic enterprise local authorities are willing to pay liberally for the right to share in the benefits offered. For example, the municipality of Königsberg in Prussia has made a ten years' compact with the Hohenstein sanatorium by which it acquires the right of filling five beds in return for a yearly subsidy of £200 and the option of sending additional patients at the rate of £45 each. The Poor-law authorities have not in general shown the same readiness to coöperate in the movement, the reason given being that as their funds are levied over small areas the cost has been found to be an obstacle. Nevertheless, the Federal Department, which acts in the place of the English Local Government Board in Poor-law matters, has ruled in one case of appeal that the treatment of tuberculous patients in sanatoriums may be regarded as falling within the province of the Poor-law authorities so long as these act on the advice of their medical officers. On the strength of this decision the city of Hamburg now hands over its tuberculous poor to suitable sanatoriums in cases where this treatment offers a reasonable chance of success. Berlin follows the same plan and also places at the disposal of persons of small means funds (in the aggregate £500 a year) assisting them to undergo treatment in sanatoriums without the aid of Poor-law relief. Special funds of the same kind have been formed at Munich, Essen, Darmstadt, and many smaller places, while a number of towns perform the same service at the public charge.

One of the most important branches of the work is that which is done by the insurance authorities—local associations appointed under the Industrial Insurance Laws for the purpose of assisting the working classes in cases of sickness and accident. These bodies have now for some years—especially in Hanover—employed a large amount of their accumulated funds in providing sanatoriums and in checking the ravages of tuberculosis in other ways, both preventive and remedial. Many of the insurance authorities have restricted themselves to advancing money at low rates of interest, the rate varying from ½ per cent. to 3½ per cent., [illegible] the Hanseatic towns, and Alsace-Lorraine, and others are now imitating their example. Even some of the Railway Pension Fund committees and the trade unions (like that of the miners in Westphalia) have entered the same field. Among the means adopted in this national campaign against disease is the dissemination of popular literature amongst the working classes both in their homes and through the instrumentality of the elementary schools. The Prussian Ministers of Public Works, of Worship, and of the Interior have even joined in the issue of an ordinance to local authorities urging them to resort widely to this method of propaganda. Of one brochure 200,000 copies have been circulated in the public schools. Conferences of teachers are also held on the subject with a view to enlist their support, public lectures with lantern illustrations are arranged during the winter months, and last winter the central committee of the sick funds of Berlin held seven courses, each of five lectures, in different parts of the city, [illegible] regular part of the pro[illegible] a tuberculosis museum [illegible] purpose being placed at its disposal by the Imperial Home Ministry in the "Permanent Exhibition for Workmen's Welfare" (*Ständige Ausstellung fur Arbeiterwohlfahrt*) in Charlottenburg.

It is too soon to judge of the crusade by results, though the results already achieved are extremely gratifying. According to returns published by the Imperial Statistical Bureau, based on the work of Dr. Mayet, the mortality per 10,000 living caused by tuberculosis of the lungs in towns of 15,000 inhabitants and over was as follows:—1877-81, 357·7; 1882-86, 342·2; 1887-91, 304·0; 1892-96, 255·5; and 1897-1901, 218·7.

On the whole, the main portion of the working classes in Germany is fairly well provided with hospitals, sanatoriums, and shelters for tuberculous patients, thanks to the enterprise shown by the insurance authorities, and the needs specially felt at the present time are (1) a greater number of institutions for the reception of women who hitherto have not had their fair share of attention and (2) the provision of institutions, to which, in return for moderate payment, patients belonging to the middle classes may resort. It is complained that between the 14,000,000 persons for whom the various insurance funds provide free treatment and the well-to-do class of people who can afford to pay for independent treatment at special institutions there is the large lower-middle class of people of restricted means to be numbered by the million who have to a great extent been overlooked by this modern crusade against disease. It has been suggested that, following the example of the industrial insurance organisations, the private insurance companies and corporations might enter this field of philanthropy if only from purely commercial and interested motives. Another lack is that of a sufficiency of institutions for the reception of the hopeless cases which, if allowed to remain at large, may act as centres of infection.

One of the measures to which the central committee is now devoting attention is legislation on the subject of compulsory notification of tuberculous disease. Already several states—Saxony, Baden, and Hesse—have enacted this precaution and while Prussia has so far held back a practically similar result has been obtained in many parts of the country by means of police ordinances. For example, in Wiesbaden a police edict requires medical men to report every case of tuberculosis of which they hear in the course of their professional work when there exists any danger of infection. The same provision exists at Frankfort-on-the-Main. In Berlin medical practitioners who attend cases of tuberculosis in hotels and lodging-houses must notify them within 24 hours. The central committee, however, aims at having notification made universal throughout the empire and to this end it is agitating for an Imperial statute. At present the committee will be satisfied with notification in the case of death from tuberculosis and of sickness in the event of a change of dwelling.

MERCURIAL POISONING OR ULCER OF THE STOMACH?

A *cause célèbre* which has occupied the attention of the Roumanian law courts for about a year and has recently come to an end presents several features of extraordinary interest both from a medico-legal and from a general medical point of view.

The case is that of a young medical man who was charged with the murder by poison of his young wife to whom he had been married about a year and the principal point round which the question of guilt or innocence turned was whether the corrosive sublimate, from the effects of which the victim was said to have died, was administered to her while alive or had percolated into the internal organs from the preserving fluid into which they had been placed after exhumation with a view to being examined. Whilst the former opinion was entertained by a number of authorities of the first rank, including university professors and well-known medical men, the latter was advanced by no less eminent men of science, including the well-known Professor Babes of Bucharest. The controversy between the two opposing medical groups became at times so acrimonious and personal that for the honour of the profession it is to be hoped such scenes will remain unparalleled, as they have doubtless hitherto been. This was probably due to the "confrontation method" of examining witnesses, which is in force in Roumania and which frequently assumes the character of a discussion between the witnesses with the judges, jurymen, and counsel interposing with questions as they think fit.

The points of accusation were as follows. The young medical man married a girl who brought him a dowry of 40,000 francs. This money being soon exhausted the accused effected a joint insurance on his and his wife's lives with two insurance companies for the amount of 50,000 francs. Shortly afterwards the young wife was taken ill and was attended in her illness by about half a dozen medical men who diagnosed the disease as anæmia and ulcer of the stomach. She died one night rather suddenly but was not seen by any other medical man except her husband until a few moments before she expired. The cause of death was certified as ulcer of the stomach and the body was buried in due course. At the funeral and shortly afterwards ugly rumours began to circulate that the medical man had poisoned his wife. This coming to the knowledge of the insurance companies and of the authorities the body was exhumed some few weeks after burial and subjected to a post-mortem examination. No ulcer of the stomach was found but 32 milligrammes of mercury and 13 milligrammes of arsenic were extracted from the gastric contents. A second and third analysis did not confirm the presence of arsenic. This was explained by the impurity of the reagents used at the first examination. On the other hand, a large quantity of mercury was detected in the walls of the stomach. The case became the exciting topic in the whole country and was sent to the Superior Sanitary Council (a sort of medical tribunal) for consideration. By a majority this authority decided in favour of the theory that the victim died from mercurial poisoning and the matter entered upon the stage of criminal prosecution. The defence was that the illness from which the deceased died could not have been chronic poisoning by mercury, as the attending medical men had never seen any of the classical symptoms of this intoxication—namely, stomatitis, salivation, and anuria. Nor could it have been an acute case of mercurial poisoning, seeing that the patient was taken worse during the night and had died within a few hours, whereas, according to Brouardel and other authorities, the shortest interval between intoxication and death is, as a rule, 24 hours, exceptions to this being very rare. Besides, the symptoms during the fatal night had not been such as to suggest acute mercurial poisoning only. There had been no pain but dyspnœa and vomiting, which are suggestive more of nephritis and uræmia. As a matter of fact, Professor Babes found when examining the kidneys signs of interstitial nephritis and also signs of ulceration of the stomach, though there was no evidence of a definite ulcer or of perforation. The opinion of the medical experts for the defence was therefore that death was not due to the action of the mercury, that there was at least room for doubt, and that it was impossible to say with certainty that the deceased had been poisoned. The mercury in the stomach might have come from the liquids used in sending the organs to and from the various laboratories, or it might have come from vaginal irrigations with sublimate solutions, it being known that the deceased had used such irrigations for some time after a miscarriage which she had a few months before her fatal illness. It was even suggested that the poison might have been poured into the organs designedly or negligently.

To these arguments the prosecution replied that the classical symptoms of mercury intoxication are occasionally absent, that it is not proved without a doubt that an acute intoxication may not end fatally in less than 24 hours, and that the organs had passed through the hands of responsible persons who had no interest in soaking them in sublimate. Moreover, even if so the poison could not have percolated into the deeper organs in such proportionate quantities, as the mercury was also found in the large intestine, the liver, the spleen, and other organs. The distribution must therefore have taken place through the circulation only, beginning with the digestive tract. As to the ulcerations of the stomach wall, they might be the result of the mercury poisoning, as might also be the case with the nephritis. The illness could not have been an ordinary ulcer of the stomach as there were no signs of perforation, and even as to the hæmatemesis the attending medical men had never seen the blood and had never spoken to the patient about it, but had placed reliance in this respect on the statements of the prisoner. To this the defence rejoined that, according to an experiment by Brouardel, mercury is diffusible post mortem through the whole organism, that the analysis had revealed comparatively large quantities of mercury on the skin and on a cloth in which the body had been enveloped, this being proof that the poison had proceeded from outside the body and not from inside. The gastric ulcerations and the nephritis could not have been due to the mercury as there would have been corresponding symptoms during life. The nephritis was quite sufficiently serious to have been the cause of death, although there was no perforation of the stomach, and as to the hæmatemesis it was immaterial to the issue whether anyone had seen the blood or not, as this is a symptom common both to ulcer of the stomach and to mercurial poisoning.

The case came for trial before a provincial assize court, when a new question arose—namely, whether mercury had been discovered in the bones of the deceased. It was thought that if that were the case it might be concluded that the poison had spread by means of the circulation and that would confirm the theory of intoxication. As the bones had not been previously examined the trial was adjourned and the examination ordered. At first 450 grammes of bones were exhumed and subjected to the necessary analysis with the result that no mercury was discovered. The prosecution demanded a second analysis and a further quantity of bones were disinterred and examined. This time mercury was found in appreciable quantities. Meanwhile the trial of the case was transferred to the capital so as to insure greater impartiality. At this second trial, which lasted ten days, the whole of the arguments were gone through again, including the finding of mercury in the bones. While the prosecution advanced this as a proof of intoxication the defence and particularly Professor Babes held their ground that the mercury could not have come from anywhere else but the preserving liquids. Otherwise mercury would have been found in the brain and muscles as well, which was not the case. Much was also made of the circumstance that the first analysis of the bones revealed no mercury, while the second did. The defence also relied upon the fact that the body of the victim was in an extremely bad state of preservation, which would not have been the case had death been due to mercurial poisoning.

At this stage the trial assumed the form of an open battle between the principal medical experts. The presiding judge had several times to remind them that they were before a number of jurymen, several of whom, by the way, were medical men, and not before a learned medical society. Personalities were thrown to and fro to the ill-placed merriment of the public, and the divergence of opinion was so pronounced that there was no possibility of bridging it over. In the end the result of the trial was favourable to the prisoner. He was acquitted, the jury rightly refusing to take the responsibility on their shoulders when the leading medical experts were so widely divided. To the impartial reader of the medical evidence the case must remain a puzzle. There were, no doubt, many elements favouring the theory of murder but, on the other hand, even the prosecution had to admit irregularities in the course of the several medical and chemical examinations, so that if it be the correct thing to let ten guilty men go unpunished rather than punish one innocent one there was sufficient doubt in the matter to justify the verdict of acquittal. To the medical profession the case is of importance as it shows that the apparently easiest cases may meet with insurmountable difficulties in the hands of even the greatest authorities.

MEDICINE AND THE LAW.

The Risk of not Writing Prescriptions.

A RECENT law case referred to in *La Semaine Médicale* points to the desirability of a prescriber always committing his prescriptions to paper. A medical man was supplied with a corrosive liquid instead of a 1 per cent. solution of cocaine hydrochloride which he clearly ordered by a written prescription. The liquid was used for producing anæsthesia preparatory to extracting a tooth. The court held the prescriber to be absolved from blame, stress being laid on the fact that the prescription was given in writing. Cases of misadventure are fortunately rare, but when they happen it is satisfactory to be able to lay the blame on the author of the mistake. In the past it has been the general custom to write prescriptions but since the advent of the telephone it is obviously an easy thing for medical men to ring up the pharmacist who dispenses for them and to dictate their prescriptions. There would seem to be no undue risk of error in such cases if only the precaution be taken to request the pharmacist to repeat the instructions. It is open to doubt whether, from another point of view, this practice is, on the whole, a good one, since the act of committing a prescription to paper is more likely to be accompanied by calm and deliberate judgment than when a batch of instructions are hurriedly dictated through the telephone.

Section 14 of the Sale of Food and Drugs Act.

The division of the sample for the [illegible] into [illegible] with [illegible]. In some instances a third part of the sample is barely sufficient for a complete analysis. The division, for example, of a sample of spirit is a case in point and the fact of purchasing a large sample is calculated in this instance to excite suspicion as to the motive of the purchase. An interesting point in connexion with this question of the division of the sample was argued in the Court of Appeal recently. A grocer was charged with having unlawfully sold to the prejudice of the purchaser four penny packets of cream of tartar which were not of the nature, substance, and quality of the article demanded, the analyst certifying that the cream of tartar contained lead in the proportion of three-quarters of a grain per pound. The inspector asked for four packets, which were all similar in size and in outward appearance and bore similar labels and were taken from the same box. The contents of the four packets were then mixed and the mixture was divided into three parts, one of which was sent to the county analyst and another to the seller, while the third was retained by the inspector. On the strength of the analysis a conviction was asked for but the justices dismissed the summons and the case came to the Court of Appeal for an opinion as to whether the justices were right in their action. The justices were of the opinion, apparently, that Section 14 of the Act had not been properly complied with since four separate purchases had been made, each packet being an article, and that mixing together the contents of the four packets and then dividing the substance so mixed into three parts did not accord with the requirements of the section. On the other hand, the prosecution contended that Section 14 had been properly complied with inasmuch as the entire purchase had been properly divided into three parts as the Act directed. The defence cited a case in which six bottles of camphorated oil were bought and it was held that "six bottles are six articles." It appears, however, that there was no division of the contents of any one bottle but two were sent to the analyst, two to the seller, and two were retained by the inspector. That was held not to be a compliance with Section 14, for it was obvious that the oil might be of different quality in different bottles. In the case of the packets of cream of tartar, however, they were all labeled in the same way and taken from the same box. The Lord Chief Justice decided that the case should go back to the justices to proceed in the matter. The appellant, he said, asked for cream of tartar which for the purpose of measurement was put up in penny packets. He asked for four packets and the court was asked to say whether because four packets of the same article labeled in the same way and sold at the same time as cream of tartar were mixed together and then divided into three parts that was a good objection to the analysis. He was of opinion that it was not a good objection and Mr. Justice Kennedy and Mr. Justice Ridley agreed.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 28, 1827.

Pharmacy in England.

In 1606, apothecaries and grocers were incorporated by 4 James I., but this union was dissolved in 1615, by charter, 13 same reign, which prevented Catholics from practising physic or pharmacy in England. This charter is confirmed (except as therein stated,) by the Act 55 Geo. III., c. 194, 1815, which was amended by 6 Geo. IV. 1825, an Act that continued but one year in force. The 55 Geo. III., now in force, is highly objectionable in many respects, for example, it commands the apothecary to keep none but wholesome drugs in his shop, so that all the active vegetable and mineral poisons, though highly efficacious in proper quantities, ought to be excluded; and yet there is a large fine, if any medicine in use, ordered by a physician, be not in the shop of the apothecary. Again, any man putting the words chemist or druggist, over his door, can act as apothecary with impunity; and still this Act is a paragon of perfection in comparison with the Irish Apothecaries Act, 31 Geo. III. c. 34, which in fact is a dead letter, for in that happy and well governed country, there are more irregular than regular apothecaries. In England the apothecaries must attend lectures on medicine and surgery, and hence called surgeon-apothecaries; they are the physicians of nine-tenths of the population, which in Ireland they practise o the same extent, without ever attending any lectures on either subject: the mistakes of these men are really frightful and most extensive. Some of them attend lectures on midwifery, and then practise every branch of medicine. They generally attend in the most dangerous cases, and prescribe a variety of medicines, and after many days, when death stares them, they recommend that proper medical aid may be resorted to; the patients generally die, and all blame is ascribed to the physician, and none to the apothecary. Again, these men are constantly out prescribing, and their shops left to the care of school-boys, who make the most fatal mistakes. There is no inspection of such shops in the provinces, and hence the most inert and useless medicines are daily compounded for the most fatal cases. The 55 Geo. III. ought to be amended, and extended to Ireland.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7916 births and 4664 deaths were registered during the week ending April 22nd. The annual rate of mortality in these towns, which had been 15·7, 15·7, and 16·6 per 1000 in the three preceding weeks, declined again last week to 15·6 per 1000. In London the death-rate was 14·9 per 1000, while it averaged 15·9 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·7 in Kings Norton, 7·2 in Newport (Mon.), 9·1 in Willesden, 9·2 in Burnley, 9·3 in Handsworth (Staffs.), 9·6 in Leyton and 9·9 in Hornsey; the highest rates were 20·3 in York, 21·0 in Hull, 22·3 in West Bromwich, 22·8 in Middlesbrough, 24·1 in Wigan, 24·3 in Tynemouth, 26·4 in Huddersfield, and 28·9 in Merthyr Tydfil. The 4664 deaths in these towns last week included 453 which were referred to the principal infectious diseases, against 433, 430, and 553 in the three preceding weeks; of these 453 deaths, 203 resulted from measles, 100 from whooping-cough, 50 from scarlet fever, 38 from diphtheria, 38 from diarrhœa, 21 from "fever" (principally enteric), and three from small-pox. No death from any of these diseases was registered last week in Hastings, Bournemouth, Handsworth (Staffs.), Kings Norton, Grimsby, Birkenhead, Rochdale, Rotherham, York, or South Shields; while they caused the highest death-rates in Southampton, Hanley, West Bromwich, Warrington, Oldham, Sheffield, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Southampton, Reading, West Bromwich, Coventry, St. Helens, Wigan, Warrington, Oldham, Sheffield, and Merthyr Tydfil; from scarlet fever in Plymouth; from diphtheria in Hanley, Bootle, and West Hartlepool; from whooping-cough in West Ham, Ipswich, Hanley, Smethwick, and Middlesbrough; from "fever" in Huddersfield; and from diarrhœa in Hanley. Two fatal cases of small-pox were registered in Southampton and one in Oldham, but not one in any other of the large towns. The number of small-pox cases under treatment in the Metropolitan Asylums Hospitals, which had been 20, 21, and 15 at the end of the three preceding weeks, had risen again to 17 at the end of last week; six new cases were admitted during the week, against two, four, and none in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, April 22nd, was 2128, against 2032, 2086, and 2133 on the three preceding Saturdays; 253 new cases were admitted during the week, against 254, 292, and 290 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 273, 308, and 304 in the three preceding weeks, declined to 272 last week, but were 18 above the number in the corresponding period of last year. The causes of 69, or 1·5 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Bradford, and in 47 other smaller towns; the [illegible] certified deaths were registered in [illegible] Smethwick, Aston Manor, Liverpool, St. Helens, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·9, 16·6, and 18·0 per 1000 in the three preceding weeks, declined again to 17·8 per 1000 during the week ending April 22nd, but was 2·2 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·2 in Leith and 15·3 in Aberdeen to 24·4 in Perth and 26·0 in Greenock. The 597 deaths in these towns included 23 which were referred to measles, 23 to whooping-cough, 12 to diarrhœa, six to diphtheria, three to "fever," and two to scarlet fever. In all, 69 deaths resulted from these principal infectious diseases last week, against 43, 73, and 69 in the three preceding weeks. These 69 deaths were equal to an annual rate of 2·1 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of measles, which had been five, 13, and 17 in the three preceding weeks, further rose last week to 23, of which 17 occurred in Glasgow and six in Edinburgh. The deaths from whooping-cough, which had been 20, 28, and 36 in the three preceding weeks, declined again to 23 last week, and included 15 in Glasgow, three in Dundee, two in Leith, and two in Greenock. The fatal cases of diarrhœa, which had been 20 and nine in the two preceding weeks, rose again last week to 12, of which four were registered in Edinburgh, three in Glasgow, two in Dundee, and two in Leith. The six deaths from diphtheria corresponded with the number in the preceding week and included three in Edinburgh and two in Greenock. The three fatal cases of "fever" occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 105, 119, and 121 in the three preceding weeks, further rose last week to 126, and were 11 in excess of the number in the corresponding period of last year. The causes of 19, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·9, 25·5, and 21·6 per 1000 in the three preceding weeks, rose again to 23·4 per 1000 during the week ending April 22nd. During the past four weeks the death-rate has averaged 23·9 per 1000, the rates during the same period being 15·5 in London and 16·2 in Edinburgh. The 170 deaths of persons belonging to Dublin registered during the week under notice were 13 in excess of the number in the preceding week and included 12 which were referred to the principal infectious diseases, against eight, five, and eight in the three preceding weeks; of these, four resulted from measles, four from whooping-cough, three from diarrhœa, and one from diphtheria, but not any from small-pox, from scarlet fever, or from "fever." These 12 deaths were equal to an annual rate of 1·7 per 1000, the death-rates last week from the principal infectious diseases being 1·3 in London and 2·2 in Edinburgh. The fatal cases of measles, which had been four, none, and four in the three preceding weeks, were again four last week. The deaths from whooping-cough, which had been one and two in the two preceding weeks, further rose last week to four. The fatal cases of diarrhœa, which had been two, two, and none in the three preceding weeks, increased to three last week. The 170 deaths in Dublin last week included 34 of children under one year of age and 48 of persons aged 60 years and upwards; the deaths of infants were 15 above the number in the preceding week, while those of elderly persons showed but a very slight excess. Eight inquest cases and four deaths from violence were registered; and 66, or more than a third, of the deaths occurred in public institutions. The causes of nine, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet, viz.:—Cecil Howard Rock (dated May 15th, 1903); Herbert Hope Gill (dated Nov. 12th, 1903); and Alexander Thomas Wysard (dated May 13th, 1904).

Fleet Surgeon A. Cropley has been placed on the Retired List (dated April 22nd).

Staff Surgeon Montagu L. B. Rodd is appointed to the Royal Naval Hospital, Stonehouse, from May 8th.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel A. T. I. Lilly is appointed to the Eastern Command. Colonel F. Howard is appointed president and Major J. Girvin, Major W. W. O. Beveridge, D.S.O., and Major T. W. Gibbard members of a medical board for the examination of candidates for commissions in the Militia and Imperial Yeomanry.

SIR JAMES HANBURY, K.C.B.

The Distinguished Service Pension vacant by the death of Surgeon-Major-General T. Walsh has been conferred on [illegible] Hanbury, K.C.B., retired. [illegible] the Afghan War, 1878-79-80, and in the Egyptian campaign of 1882 are well known. As regards the latter expedition it will not be forgotten that the medical arrangements gave rise to a Government inquiry by Lord Morley's committee and to the publication of a big blue-book thereon. There was never an occasion, if all the circumstances and exceptional conditions of that expedition be taken into account, on which the Army Medical Service rendered better or, judging from the results, more successful service than in the Egyptian campaign of 1882 and this was, we believe, the opinion formed by every impartial and competent reader of the evidence and report published by the War Office committee at the close of its inquiry. As principal medical officer of the Madras command, a post which he held before his retirement in 1892, Sir James Hanbury fully maintained his reputation and the respect in which he had always been held.

ADMIRAL SIR A. W. MOORE, K.C.B., C.M.G., AND THE EGYPTIAN WAR OF 1882.

The recent notification by the Admiralty of Vice-Admiral Sir A. W. Moore's appointment as second in command of the Channel Fleet recalls to mind the services which this officer rendered in the Egyptian war of 1882 when in command of the naval flotilla on the Sweet Water canal in connexion with the transport of the sick and the wounded. Admiral (then Commander) Moore was present at the occupation of Ismailia and the battle of Tel-el-Kebir and was responsible for the organisation and management of the naval flotilla designed for the transport of stores [illegible]k and wounded to [illegible] efficient aid was [illegible] be safely said that never, perhaps, were wounded men more safely and comfortably conveyed to their destination from the immediate vicinity of a battle-field (Tel-el-Kebir) than on the occasion in question.

THE WOUNDED IN MODERN NAVAL WARFARE.

It seems certain that a [illegible] battle will soon take place [illegible] Russian fleets in Eastern [illegible] losses on both sides will be very heavy. The greater part of Admiral Rojdestvensky's fleet has left Kamranh for somewhere unknown at the present moment to meet its Japanese enemy, whose exact position has not yet been revealed. It is not too much to say that the result of any engagement of the fleets in "being" is universally awaited with extreme interest, for under existing conditions there is so much to be learned and not least so in regard to the best naval medical arrangements that can be practically adopted in the circumstances. Writing last year in the *Deutsche Revue* Vice-Admiral D. Paschen of the German navy lays down the law from a combatant's point of view regarding the manner in which men who are wounded in the naval engagements of the future should be treated. On help for wounded men in a sea fight much, he says, has been written and much has been said. When, however, anyone is called upon to explain the actual state of the question it is still necessary to lay stress on the fact that no serious treatment of wounded men can be undertaken until after the combat is over. During the action the injured, save for such aid as their comrades can afford them, must be entirely abandoned for as long a time as the circumstances may demand. The commander of a warship is compelled to look upon wounded men as a hindrance and for this reason alone he would be anxious to get rid of them as soon as possible even if he were not naturally desirous that they should have the same advantages as those who sustain injuries in battles on land. Unfortunately, the conditions under which naval warfare occurs do not favour this; on the contrary, they are most unfavourable. All civilised States have provided hospital ships for service on the high seas in the event of war, but according to the best authorities it is absolutely necessary that these vessels should keep well out of the way as long as active hostilities are in progress. Even if a suspension of hostilities should take place it would not be possible to allow a hospital ship to intervene between the combatants. The issue at stake must be decided one way or the other before officers in command can permit themselves to think of anything else. So long as war continues upon this earth we have to look upon battle as the sole means of securing peace. Anything that interferes with the proper conduct of a battle would in all probability give rise to a hundred times as much pain and suffering as were for the moment relieved. Commanders can only think of how they can best conduct their battles to the bitter end. They cannot allow themselves the luxury of humanity. Of course, none would commit superfluous acts of cruelty, but, on the other hand, no merciful precepts can be allowed to jeopardise the issue of an engagement. It is quite impossible to do as much for wounded men at sea as it is on land. On the field of battle stretcher-bearers can go under fire if they choose to do so; it is simply a question of personal courage. Their presence at the fighting line does not interfere with the fighting and the fighters do not interfere with them. We have no recent experience of a naval battle on a large scale but having regard to their high rate of speed the area covered by war-vessels during an engagement will inevitably be very large and the zone outside which neutral ships have to keep must be correspondingly wide. Should a neutral vessel attempt to afford aid during a battle to a damaged man-of-war it would probably find itself inside the danger zone just when it was about to commence work. In such a case no commander would let mercy interfere with his manœuvres and no State is consequently able to guarantee the inviolability of hospital ships. For their own sake these vessels must keep completely out of the way and be especially careful to avoid the risk of capture by the enemy. Admiral Paschen lays down the rule that the fall of the flag, indicating the unconditional surrender of a warship, may be taken as a signal that hospital ships are free to approach the scene of action, but a little further on he adds that free access for neutral vessels is only permissible when the commander of the victorious fleet is of opinion that there is no danger of his prizes being recaptured. The post of the officer in charge of a hospital ship is, indeed, full of difficulty. He and his crew have to be sailors as well as medical men and must excel in both capacities. Admiral Paschen next describes the circumstances of the wounded on board a warship in action. Light and air, he says, can only be obtained by renouncing the protection afforded by the armoured portion of the vessel and yet it is here that such dressing as is possible during a battle must be carried on. Behind armour plates the wounded and their attendants are safe from the missiles of the enemy and have only to encounter general risks such as explosion and foundering. But with all the boilers in activity and every aperture hermetically closed the horror of the situation can be imagined, especially if, as is most probable, the electric light has gone out. Wounded men can only be moved during the pauses in an engagement. They have for the most part to remain a long time in the places where they were injured. It is therefore of the utmost importance that the crews of men-of-war should be taught the elements of practical surgery and especially how to stop bleeding. In conclusion, Admiral Paschen gives a historical account of the various conventions and leagues which have for their object the alleviation of the preventable hardships which are a blot upon naval warfare.

THE WAR IN THE FAR EAST.

There is one point which calls for notice at the present time and before the subject of the capture of Port Arthur is finally relegated to things of the past. The *Times* of April 20th gives some very startling facts and figures, extracted by its correspondent at Tokio from the official record of the capture of that fortress. It seems that the number of serviceable guns was 528 and that the stores of ammunition and food-supplies were enormous. The prisoners included 41,641 combatants, of whom some 15,307 were sick or wounded. To a soldier it must appear astounding that Port Arthur surrendered in such circumstances. Looking back on the Boer war Sir George White's garrison at the time of the relief of Ladysmith had only food-supplies (such as these were) for 48 hours, if we remember aright, and the troops bore the unmistakeable marks of a more or less chronic state of starvation.

The *Novoye Vremya* has published some interesting impressions gathered from members of the Russian medical staff who were left behind at Mukden and were sent by the Japanese into the Russian lines. The sanitary condition of the Japanese troops was good and the men had stood the cold well. They were all well clad. The Russians found that nearly every Japanese officer knew either their own language or a foreign one, generally English, while the Japanese medical staff were familiar with German.

Correspondence.

"Audi alteram partem."

THE CAUSATION OF LEPROSY.

To the Editors of THE LANCET.

SIRS,—I see that in THE LANCET of March 11th Mr. Jonathan Hutchinson is using some remarks of Dr. Armauer Hansen to back up his theory that leprosy is not contagious. I cannot, just at present, obtain the article from which the extracts are taken, but judging from letters I received from Dr. Hansen some time ago, I am under the impression that Mr. Hutchinson is deducing a great deal more from Dr. Hansen's article than was intended by the author. I do not wish to discuss the question of the contagiousness or otherwise of leprosy. I believe it is contagious and Dr. Robert Koch told me a few months ago that in the Baltic provinces of Germany, where lepers are scarce, it was easy to trace infection from case to case. Mr. Hutchinson, believing that leprosy is not contagious, would do away with all leper asylums. He speaks of "those who are responsible for the miseries of Molokai and Robben Island." Of the condition of affairs at Molokai I knew nothing. Of Robben Island I do. I have spent more weeks on that island than Mr. Hutchinson has hours and am in a far better position to offer an opinion on it than he is.

I maintain that, apart from the suffering inevitably caused by the disease, the use of the word "misery" as applied to Robben Island is misleading. Even if Mr. Hutchinson were able to prove conclusively that leprosy is not contagious, that certainty would not do away with the necessity for such places as leper asylums. In the vast majority of cases, especially outside asylums, a time comes when the leper is unable to support himself and, speaking from a wide knowledge of the social and financial position of lepers in South Africa, very few of them possess sufficient means to support themselves. To do away with leper asylums would imply starvation and misery to most of these unfortunate people. Lepers sometimes escape from the Pretoria Asylum, return to their kraals, and after a longer or shorter absence are either captured or, and this is by no means infrequent, return of their own accord. On readmission their condition has always proved to be very much worse than when they left. A fortnight ago a white leper returned to the asylum. He escaped on Nov. 30th, 1904, and went to the farm of a relative in the Spelonken. When he left he was well able to do a good day's work. On his return, after little more than three months' absence, he had altered so much for the worse that at first I could hardly credit it was the same man and he had to be brought to the consulting room in a barrow. Since these poor creatures are unable to provide themselves with food, still less the medical attention so essential to them, it must be provided by the State, and the State can only provide for their wants efficiently and economically by means of asylums.

It must be taken into consideration that those who are able to provide for themselves are not compelled to enter an asylum, at least, not in this colony. I have this morning received a visit from a former patient; the disease in his case has been arrested and as he has means he lives on his own farm. On the other hand, there are several arrested cases in the asylum at this time; I should be glad to get rid of them but I cannot turn them out to starve. They are not dangerous but though in good health are so mutilated that they cannot work. Leper asylums will, I am afraid, be necessary for some time to come, just as lunatic asylums. No one would select either of them as a place of residence, but the comfort of those who are compelled by circumstances to enter them is not enhanced by reckless assertions which imply that they have been needlessly inconvenienced.

I am, Sirs, yours faithfully,

GEORGE TURNER,
Medical Officer of Health of the Transvaal; Resident
Medical Superintendent of the Pretoria
Pretoria, April 2nd, 1905. Leper Asylum.

THE TENURE OF PUBLIC HEALTH APPOINTMENTS.

To the Editors of THE LANCET.

SIRS,—The accounts which you gave in THE LANCET of April 15th of the treatment of two medical officers of health ought to be enough to convince the strongest opponent of the Public Health Bill (security of tenure of office) of its necessity. Dr. F. T. Bond's treatment is simply a scandal and must surely open the eyes of the public to the need of reform. The Local Government Board has now been placed in an extremely awkward position by the defiant attitude of the Chipping Sodbury district council in electing a local practitioner in opposition to the strongly worded advice of the Board. The officials at Whitehall may be trusted to act justly in the matter but they must see that the recurrence of such incidents may at any time occur unless steps are taken to prevent it by giving us security of tenure of office. If they knew, as I do, of the intolerable position in which many medical officers of health in rural districts and small towns find themselves they would not hesitate for a moment in helping forward our Bill.

I am, Sirs, yours faithfully,

April 22nd, 1905. HERBERT JONES.

THE RECENT DISCUSSION ON CANCER IN BERLIN.

To the Editors of THE LANCET.

SIRS,—I shall be greatly indebted to you for your courtesy in permitting me to notice in your pages certain items of the recent discussion on cancer which took place in Berlin on March 8th, 15th, and 22nd.[1] The following remarks will be restricted to the contributions made to the debate by Dr. L. Pick, Professor F. Blumenthal, and Professor D. von Hansemann. Dr. Pick spoke chiefly of chorio-epithelioma and of the comparisons which may be made, and which, indeed, have already been discussed by me in your pages, between ordinary cancer, chorio-epithelioma, and the phenomena which take place in the early history of the trophoblast of normal gestation. He showed the gradual passage from ordinary chorio-epithelioma and he demonstrated that in some cases of the former certain portions of the tumour exhibited the structure of an ordinary carcinoma. In fact, Dr. Pick's researches furnish a new proof, *from the pathological point of view*, of the truth of the statement that cancer is an irresponsible trophoblast. In reply to Dr. Pick's remarks, Professor von Hansemann again referred to the recent finds of Schmorl.[2] The supposed import of these discoveries is, however, easily disposed of. The objections raised are: (1) That, as Schmorl found in the lungs of women in advanced pregnancy or shortly after birth, "normal" trophoblast or chorion exhibits no powers of indefinite growth, and (2) that these powers are manifested only by "pathological" trophoblast, such as occurs in hydatid mole. But the results of embryological research of the past 15 years, the work of Hubrecht, van Beneden, Hill, Duval, myself, and others, place Schmorl's finds in another light The chorion or trophoblast of mammalian development is a thing which is not embryonic but pre embryonic in origin,[3] and which normally has a very short life The period of its functional activities as I demonstrated some years ago varies but is a fixed time for the species it is 15 days in the rabbit, 22 in the cavy, from 28 to 30 in the sheep, and from 45 to 47 days in man, &c From this period, the critical period of my researches it begins to degenerate under the influence of the altered, now pancreatic, digestion and *at or near the close of a normal gestation in man there is no such thing as "normal" trophoblast* Months before that time it had entered upon its long slow course of degeneration Hence Schmorl's finds have no bearings upon Dr Pick's (or my) conclusions but they are quite in accord with, and indeed might have been predicted from, my work[4] of years ago But in three cases *out of the early days of gestation* Schmorl found that the trophoblast exhibited the characters of unlimited growth—i e , instances of pre critical or critical abortions &c Here we have to deal with what Professor von Hansemann terms "pathological" trophoblast But it is only "pathological' in the senses that "the embryo" is absent or aborted and that the trophoblast still retains all those powers of erosion and of unlimited growth which indeed characterise the pre critical trophoblast of normal gestation No new powers have come to it , there has been no change in its properties , it has simply not commenced to degenerate for the change of nutrition of normal gestation is lacking in the absence of a completed embryo

[2] Verhandlungen der Deutschen Pathologischen Gesellschaft, Jahrgang 1904, Heft 2, pp. 39-46.

Professor Blumenthal's finds concern the chemistry of cancer As he stated, in their essentials they have been made independently by Neuberg, Wolff, and Bergell in Berlin They confirm and extend my recent conclusions in other directions Briefly, they have found that (1) the substance of cancer cells is quite different chemically from that of somatic cells, (2) the pigment of melano sarcoma is not the same as any pigment occurring in the normal body , (3) cancer cells contain much albumin and little globulin , (4) substances are present in cancer cells which hitherto have not been found in the healthy body , (5) the cells of cancer are much more delicate and they are more easily destroyed than cells of normal tissues , (6) pepsin attacks cancer cells with difficulty, *while trypsin easily and quickly dissolves them* , and (7) a ferment occurs in cancer cells, that first described by Eugen Petry, which possesses the property of digesting not only the albumin of its own cells but it can also completely dissolve all the cells of the body, while ordinary somatic cells contain a ferment which can auto digest the albumin &c , of these cells alone Add to these that in a more recent writing in No 15 of the same journal (p 443) Professor Blumenthal mentions that this cancer ferment is intra cellular, and it is possible to maintain that the above results furnish as strong a support of my standpoint as could be desired It would seem to follow from these researches that trypsin, perhaps better when aided by other secretions poured out into the intestine, as Dr John A Shaw Mackenzie has suggested, can destroy the cancer ferment malignin[5] In the ferment malignin discovered by Petry, we have a substance which can erode and dissolve practically any normal tissue of the body The only other known normal cells which possess these powers are the cells of the pre-critical trophoblast (or the same cells in hydatid mole or in chorio epithelioma) One small piece of chemical research alone remains to be made to complete the chain This is to discover the like ferment, malignin within the cells of the normal trophoblast of early gestation I am absolutely sure of its existence there, for without this ferment the cells of the trophoblast could erode neither their way into the maternal tissues nor through the walls of the oviduct in a tubal gestation, nor could they do any of the other things which, on occasion like the cells of an ordinary cancer, they can effect A very interesting and important portion of Professor Blumenthal's speech was devoted to the cancer cachexia He has concluded that this hetero lytic intracellular ferment, malignin, can auto digest in the body the cancer cell , thus the ferment can become freed get into the circulation and so by its activities cause untold destruction in other parts of the body

The etiology of carcinoma as an irresponsible trophoblast received confirmation from the cytological side from the researches of Farmer, Moore, and Walker , it is now strongly reinforced from the pathological side by the results of Dr Pick The embryological solution of the cancer problem, to all appearance, would also be the physiologico chemical one, for trypsin can dissolve the cancer cell with ease and it would appear to destroy the cancer ferment too For some time now in many countries and by many investigators attempts have been made to find a "serum' capable of dissolving the cancer cell It is, perhaps, not too much to say that these have all been in vain In your pages of Feb 4th 1905 I stated that trypsin was this substance , on Feb 11th Dr Shaw Mackenzie independently confirmed this and for other reasons , and now Blumenthal, Bergell, Neuberg, and Wolff all independently state that while the cancer ferment malignin can dissolve any somatic cell the cancer cell is easily destroyed by trypsin So that now the import of trypsin, alone or aided by substances which increase its action would appear to be indicated in the medical treatment of cancer by the researches of six different observers Blumenthal Bergell, Neuberg, Wolff, Shaw Mackenzie, and myself As a corollary to these may be cited the finds of Professor B Moore and colleagues,[6] which to my mind go to prove that cancer cells take from the blood for their own purposes those substances from which the organism usually forms hydrochloric acid in aid of its gastric digestion

I am, Sirs yours faithfully,

J BEARD

THE TREATMENT OF FOLLICULAR CONJUNCTIVITIS

To the Editors of THE LANCET

SIRS,—Of late a high authority has stated that follicular conjunctivitis can scarcely be called a disease on the ground that its microscopical appearances are apparently identical with the structure of the follicles in lymphatic glands Whatever the anatomical appearances may suggest there are two facts incompatible with this view—viz , the disease is contagious and responds most promptly to treatment In the Croydon municipal schools the disease was very common but in two years we have reduced the number of cases by at least one half The fact that the disease is contagious must not be construed as implying that it is necessary to exclude the children who have it from the schools It would be going too far to say that the disease is innocuous It was held for many years that these cases were predisposed to granular ophthalmia and not improbably this is true, for the conjunctival tissues being enfeebled by a very chronic inflammation must surely have diminished powers of resistance, and the hypothetical reason why the disease does not oftener pass into the more serious granular type is because the contagion of the latter affection is fast vanishing from the schools and indeed, from the community at large In the Croydon schools, containing 25,000 children, we have succeeded in reducing the cases of granular ophthalmia to about three It is clear therefore, in this instance that there is little chance of any of the follicular cases being exposed to the danger of infection with trachoma

When a child is found to be suffering from follicular conjunctivitis our routine is (*a*) to inform the parents that the child has a contagious disease of the eyes; (*b*) to urge them to see that the child never touches his eyes without washir [illegible] t children can attend school [illegible] with a saucer and lotion to [illegible] event of their touching their eyes , and (*d*) that the child will require a little attention at the hands of their medical attendant, or if this is not expedient at the eye department of a hospital In severe cases occurring in more well to-do children a note is sent to the medical attendant advising the treatment with cocaine, argyrol, and adrenalin. In practice several varieties of the disease occur. The simplest is that so often found after using unsterilised atropine drops for considerable periods. This rapidly subsides on discontinuing the drops and seldom calls for active treatment. In another variety, the commonest, the follicles are few in number and the conjunctiva is slightly, if at all, reddened. In a third variety for which the line of treatment outlined below was designed the follicles are exceedingly numerous, red, and opaque. Several such cases I have followed for over a year, and under the ordinary routine of hospital treatment, so far as I could see, they did not improve in the least.

---

[3] In the pregnant uterus of the armadillo Praopus hybridus now in my possession there are seven well formed identical fœtuses within the one chorion The latter was there before any of the seven and they arose within it by the independent development of seven single cells

[5] [illegible] As sp se of malignic [illegible] To distinguish the cancer ferment from pepsin trypsin secretin, &c , I now suggest the convenient and natural name of malignin

[6] B Moore W Alexander R E Kelly and H E Roaf On the Absence or Marked Diminution of Free Hydrochloric Acid in the Gastric Contents in Malignant Diseases of Organs other than the Stomach Proceedings of the Royal Society London March 16th 1905. (A full abstract of this paper is published in THE LANCET this week.—ED L)

Whatever the variety the following treatment seems infallible. The follicles are painted with cocaine and the lids are held from the eyes. After the drug has been absorbed the follicles are crushed and emptied by trituration and pressure between the two thumb-nails, one nail being next the conjunctiva and the other outside the lid. The third step is to paint the diseased part where the follicles are with argyrol, 20 per cent. After giving the membrane sufficient time to absorb the drug—say, a couple of minutes—the argyrol in the tissues is fixed there by painting on a little adrenalin, 1 in 1000. Cocaine should not be instilled in the ordinary way or the cornea would certainly be damaged irretrievably by the powerful silver salt. The sole object in using the adrenalin is to prevent the blood and lymph from washing away the germicide before it has done its work thoroughly. Two most inveterate cases were cured in three weeks; they were by far the worst cases I have ever seen. The treatment has been mostly in hospital but several practitioners have carried it out in their surgeries with equal success. For home use the patients are ordered lot. hydrarg. cyan., 1 in 10,000, with instructions to wash the eyes with the lotion by means of cotton wool. A little of the lotion is allowed to go inside the eyes but not enough to cause smarting or pain, the idea being that it is better to have a small quantity at work for a considerable time than to use it in such a quantity as will provoke a rush of tears and therefore prompt removal of the irritant. A bland ointment is used at times for the edges of the lids at night, but when it is ordered the patient is warned that it may disagree, and he is advised to discontinue if it causes the lids to be very red in the morning. The paintings are done about every other day.—I am, Sirs, yours faithfully,

CHARLES WRAY, F.R.C.S. Eng.,
Surgeon to the Western Ophthalmic Hospital; Ophthalmic
Surgeon to the Croydon General Hospital and

IF TUBERCULOSIS SHOULD BE CERTIFIED, WHY NOT SYPHILIS?

To the Editors of THE LANCET.

SIRS,—Dr. E. H. Douty's letter in THE LANCET of April 8th, p. 956, raises a question which must often present itself to the mind of the medical man. May I attempt to give an answer to it and the reason of the answer, premising first of all that in order to know how to prevent syphilis it is not enough to have made a study of syphilis; it is necessary also to have made a study of the means of preventing it. The answer is, that we do not certify syphilis because we wish to prevent its spread, not to increase it. It is very natural, and sounds very logical, to argue from tuberculosis to syphilis; but the analogy is verbal and not practical, for there is one deep-lying difference which vitiates the whole argument. The two diseases which Dr. Douty invites us to certify are in their nature the most concealable of diseases and they are diseases which there is the strongest possible motive for concealing. To make them notifiable—that is, if it means anything at all, to make them liable to compulsory detention and treatment—is to add a fresh and powerful motive for concealment without adding in any appreciable degree to its difficulty.

I am not speaking without warrant. If Dr. Douty would turn to the reports and communicated papers of the International Society "Pour la Prophylaxie Sanitaire et Morale," of which the French Society he refers to is an offshoot—volumes which certainly ought to be found on the shelves of every medical library—he would find this subject discussed from every point of view, would find the very greatest anxiety on the part of medical men to introduce notification as a means of ensuring treatment, and would find them constantly recognising at the same time that to introduce such a measure is to drive the patient away from the medical man who will notify him to the quack who will not, or to nostrums with which he can treat himself, and that the measure is therefore worthless unless accompanied by the most drastic provisions for the discovery and dragooning of these patients—provisions either ludicrously incapable of application or which have been applied again and again with the same result, the continued increase of disease. The result of long experience on the continent comes to this, that compulsory treatment, while it fails to "stamp out" syphilis, does stamp out voluntary treatment in any class to which it is applied. Accordingly, in Italy, where they have now established a vast system of gratuitous treatment, they are doing away with compulsory treatment even of the lowest class of woman in the belief that the voluntary system will prove more efficacious. In England, on the other hand, the Physical Deterioration Committee of last year, adopting the view expressed by Sir Victor Horsley and some others, recommended an inquiry with a view to two measures—notification and the provision of gratuitous treatment.

Now it is obviously of the greatest importance that there should be adequate provision for the treatment of these patients and every inducement to seek it, and the fact of such provision being made by the State would doubtless attract patients and make early and prolonged treatment much more common; but to introduce at the same time a measure like notification with its necessary corollary of compulsory detention or supervision is precisely the way to drive the willing patient from the doorstep and make the outlay incurred in providing gratuitous treatment a mere waste of public money. Those who advocate these measures have not considered what they mean from the point of view of the patient. They mean that from the first confession of syphilis the patient ceases to be a free agent and we may be very sure that where this is the case the confession will not be lightly made. I am not without sympathy for the impatience of medical men who, like Dr. Douty, see this scourge raging around them and are ready to seize on any weapon which seems to offer the means of combating it. But experience proves that this is a matter in which it is fatally easy to make things worse in trying to make them better. Bad as things are at present, they are in England, by every test that can be applied, steadily becoming less bad, and however desirable it may be to hurry improvement it is still more desirable not to risk checking it.

As to sanatoriums for syphilitics, while fully recognising the value of fresh air in these cases it has to be remembered that people of the comfortable classes can get fresh air without sanatoriums and that people of the not-comfortable classes mostly have families to support. Sanatoriums, whether for tuberculosis or syphilis, can afford only a very limited remedy and it seems almost like a satire on our civilisation to take here and there one out of our overcrowded, underfed, and drink-sodden population, feed him up for a few months with good food and fresh air, and then send him back to the old conditions. The garden city and the farm colony are surely a truer prophylactic. As to education, the continental experts are absolutely agreed. It is the first thing to be done. With your permission I should like to say a few words on this subject in another letter.

I am, Sirs, yours faithfully,
B. LEPPINGTON,
Member of the International Prophylactic Society.
Oxford, April 10th, 1905.

SHOCK AND COLLAPSE.

To the Editors of THE LANCET.

SIRS,—Dr. C. Powell White in his letter in THE LANCET of April 15th, p. 1029, says that I have produced no evidence that increased atmospheric pressure is of value in the treatment of shock and that the statement rests upon my assertion alone. He has evidently not read my lectures very carefully or he would hardly make such a statement. A series of careful experiments to prove this point were carried out by Crile and are referred to in my second lecture on p. 782. The experiments themselves are recorded in Crile's book, "Blood Pressure in Surgery." Dr. White asks me to explain how the vaso-motor system is able to compensate for variations in external pressure. I thought I had already explained this in my lectures. Compensation is obtained by alterations in the calibre of the blood-vessels—that is to say, the vaso-motor centre compensates for external influences by altering the capacity of

the circulation. Dr. White in his last letter says that localised external pressure by altering the distribution of the blood will cause the blood pressure to be increased and argues from this that the phenomenon is a purely physical one. I do not, however, agree with this statement.

In a normal individual localised external pressure will *not* cause any rise in the blood pressure, as the vaso-motor centre at once compensates for any alteration in pressure which tends to take place. Thus compression of the abdomen in a healthy person causes little or no alteration in the blood pressure, while the same amount of compression in a patient suffering from shock will result in a considerable rise in the blood pressure. I would suggest to Dr. White that he should carry out a series of experiments to test the value of his assertions. I am sure that he will agree with me that arguments not based upon experiments are of little value in discussions on morbid physiology and I believe that if Dr. White carries out such experiments he will not long hold his present views. Many of the problems in relation to the blood pressure in health and disease which have been touched upon in this discussion give ample scope for further investigation along experimental lines. I do not think that arguments unbacked by experimental proof can be of much value and I trust that Dr. White will aid the cause of morbid physiology by testing his ideas by experimental research.

I am, Sirs, yours faithfully,
Cavendish-place, April 17th, 1905. P. LOCKHART MUMMERY.

POISONING BY THE WASTE GASES OF THE MOTOR-CAR.

To the Editors of THE LANCET.

SIRS,—In the course of the last few years the public has been brought in contact with the petrol engine as a result of the latter being adopted for road traction. I have seen no mention in the medical or motor papers, nor I am sure are owners of cars and their mechanics aware of the danger of inhaling the waste gases. That this danger is a serious one the following instance will demonstrate. In a room of about 2000 cubic feet capacity, the doors and windows of which were closed, four men for the space of 20 minutes were engaged in testing an eight horse-power engine, which they allowed to run and to rest for alternate intervals of two minutes and one minute respectively. Before the completion of the trial two of the men went out complaining of "feeling bad" and had nausea; their fellows who persevered with the trial were subsequently sick and all four complained of violent headache, throbbing of the temples, and of a feeling as though their heads would burst. All were able to resume work the following morning, but one came to see me some two or three days later with recent and marked anæmia, and although previously in perfect health developed in the course of a few days a large carbuncle. The symptoms I have narrated seem to point to poisoning by carbon monoxide and should act as a warning to others.

I am, Sirs, yours faithfully,
Wimbledon, S.W., April 17th, 1905. W. B. WINTON.

THE "CURE" OF CANCER.

To the Editors of THE LANCET.

SIRS,—Many surgeons will regret to read the somewhat pessimistic article under the above heading published in THE LANCET of April 15th by Mr. Edmund Owen. Looked at with the "cold and unemotional eye" of surgery it is literally true, but most, I think, will agree that Mr. Owen is unduly sensitive when he is unable to satisfy himself of having cured the case he quotes (the nature of which, by the way, he does not state was verified by microscopical examination), notwithstanding that the patient has remained free from recurrence for over a quarter of a century. There is a good deal in medicine and surgery which is incapable of absolute mathematical demonstration and it is obvious on Mr. Owen's argument that no case of cancer could ever be claimed to have been cured by operation, because if the patient lived to 100 years and passed 50 without a recurrence, dying eventually, as Mr. Owen's case seems likely to do, from old age, it could always be argued that if he had lived to 120 he might have had a recurrence. He could not therefore be claimed to have been cured, even though he lived to a ripe old age and died from something else. Such an argument is, no doubt, logically free from flaw but most surgeons will be satisfied that Mr. Owen has obtained a cure and the patient is no doubt satisfied of it herself. Indeed, "wonderfully well and active and in her eighty-fourth year," and free from recurrence after a quarter of a century, I venture to think that it would be difficult to convince her of the contrary. Mr. Owen says that the most the surgeon can promise his patient is that he will "do his best." Clumsy comfort, indeed, for the unfortunate sufferer from this terrible disease. Moreover, the patient will have taken that much for granted before he ever consulted the surgeon. Everybody admits that the three years' limit is an arbitrary one. Everybody admits that cancer cells or germs can apparently lie dormant for years, can then cause recurrence, belie hopes, and spoil statistics (though it remains to be proved that some of these recurrences are not independent outbreaks of the disease, in which case they will fall into exactly the same category as Mr. Owen's broken thigh bone or abscess of the hand).

But granted all this, are we not, I would ask, in the light of recent results, justified in giving our patient just a *little* more encouragement than that we shall "do our best"? Surely we are. Surely our attitude to our patients should be one of distinct encouragement, begotten of the vastly improved results of operation in recent years, more especially as this encouragement is our most powerful weapon in the education of the public in the paramount necessity of early recognition and early operation. When the public are educated up to and encouraged to the fact that they can be cured then we shall see fewer of the "too late" cases and our percentages of cures will go up. And if it be conceded that cancer in the first instance is a local disease it must be admitted that every case of cancer, if it could be seen early enough and removed early enough, is curable. What has led to the vastly improved results of operation in recent years? It is the fact that the surgeon now operates with the thoroughness begotten of the hope, the expectation, the determination to eradicate the disease, not in the slipshod fashion of the man of 30 years ago who was convinced of the utter hopelessness of the complaint which he was dealing with. What is required to still better the results? The encouragement in the public that it is possible to cure them. Mr. Owen's simile of the bottle thrown out to sea turning up again after years adrift is apposite so far as it goes. But he omits to record the fact that the bottle frequently does not turn up at all. Moreover, Mr. Owen admits that in certain cases operation can bring lasting relief. What is this but cure? I cannot see the difference. At all events it is a good enough cure for the patient, even though it may not satisfy the "cold and unemotional" mind of the surgeon.

I am, Sirs, yours faithfully,
CHARLES P. CHILDE, B.A., F.R.C.S. Eng.,
Assistant Surgeon, Royal Portsmouth Hospital.
Southsea, April 20th, 1905.

PIROPLASMOSIS OR RED-WATER FEVER.

To the Editors of THE LANCET.

SIRS,—In examining a number of blood films for nematode infection I have chanced to come across a case of piroplasmosis. The hæmosporidia are to be seen, both intracorpuscular and free, in the blood plasma. Seven years ago the patient spent some two and a half years in America, where I conjecture that some insect, probably a tick, inflicted an infective wound. I should esteem it a great favour to learn through your columns whether this disease has been noticed to have affected man previous to the present time.

I am, Sirs, yours faithfully,
Birmingham, April 24th, 1905. J. DENCER WHITTLES.

UNFORTUNATE ADVERTISEMENT.

To the Editors of THE LANCET.

SIRS,—The columns of the *Times* to-day contain an article dealing with the work done by St. Bartholomew's Hospital, written in a style which may have its attractions (for some readers) and has for its object the increase of the income of the hospital, but surely it is not necessary to pillory "the stoutish man, black-bearded and with bald crown of shining pallor," and why should the house surgeons and dressers be brought before the public and described as "lithe and alert men with a firmness of mouth, a quiet grip in the eye" (*sic*), and dubbed "Young Davids, sworn enemies of death and saviours of life." Surely a remonstrance from members of the surgical staff would compel

the reformatory at Whalley. At the last meeting of the Manchester city council attention was drawn to a payment of £2009 on the precept of the Lancashire Inebriates Act Board for 1905-06, an increase of £400 on the previous year. The cost, it was said, is constantly increasing. There were 66 inmates at Whalley last year, 30 being sent from Manchester and 24 from Liverpool. These 66 in the year cost £12,657 and the capital expenditure on the buildings and the land was £95,338. The council was reminded that at the Grove Retreat for Inebriate Women at Fallowfield 25 patients were dealt with last year at a cost of £869. The chairman of the watch committee reminded the council that in December the matter was considered and he then stated that the cost was about £1 13*s.* 6*d.* a week for each inmate and he did not suppose that it would ever be much less than 30*s.* a week. As the council had agreed to join in this county scheme he did not think it quite dignified to be always harping on the expense. No doubt. But all over the country there is the same feeling of irritation as regards the lavish expenditure on institutions of all sorts and in almost every other direction in which councils, whether of city or county, can vie with each other in showing their disregard of the old saying that the coat should be cut according to the cloth.

Chrysanthemum Smoking.

In December last Mr. A. W. Martin, the medical officer of health of Gorton, recommended the smoking of dried chrysanthemum petals as "a pleasant and harmless substitute" for tobacco. Perhaps he thought that it would be a gentle mode of weaning those in danger of becoming slaves to the pipe or providing a pleasant substitute for those with whom tobacco did not agree. But a case has been reported of unlooked for improvement, attributed to chrysanthemum smoking, in a person who had been "a victim for 15 years to frequent and violent epileptic fits due to chronic dyspepsia." He smoked his first pipe on Jan. 1st and began at once to improve, so that now he is "able to take his half-hour's walk without a stick, instead of being afraid to cross a space of nine feet with it; he can get six nights' rest out of seven, instead of one out of four, and can even attend church." However sceptical anyone may be as to the cause of the improvement and however mindful of *post hoc propter hoc*, the patient is to be congratulated. He adds that the flowers act best when mixed with cascarilla bark, as suggested by Mr. Martin. Should this case attain much publicity there will soon be a run on chrysanthemum blooms.

Ill-fed School Children.

The underfeeding of children in our elementary schools has been much discussed of late and wide sympathy has been aroused. But while all would seek to relieve suffering whether in young or old, it is desirable before going impulsively into schemes which may turn out to be ill-considered first of all to ascertain the facts. In Manchester Dr. A. Brown Ritchie, the medical officer to the Manchester education committee, considers that the question of underfeeding has been a good deal exaggerated. This is not to be wondered at, for the idea of children half-fed, and suffering from the painful gnawing of chronic hunger, going through their daily school tasks while physically unable to use what powers of mind they possess, is one that humane people would not endure. He thinks that the number underfed from the poverty of parents is smaller than is supposed. The appearance of privation might not be due to underfeeding so much as to ill-directed feeding, as, for instance, the diet of bread and tea on which many children live. An inquiry is now being made dealing with about 12,000 children which will show the amount and the causes of underfeeding. A small but interesting investigation carried out a little time ago regarding backward children in the schools threw some light on the problem of underfeeding. "Out of 450 backward children 325 were ill-nourished and in a low state of health, while in 111 cases the children were seriously ill-nourished." Backwardness is, says Dr. Ritchie, in the vast majority of cases due to bad health or irregular attendance apart from bad health. The bad health, of course, may or may not be connected with underfeeding. 'Many of these children seem underfed or ill-nourished, some suffer from chronic disease—e.g., tubercle—others have disease of the ears or defective sight. Many are very dull or slow mentally but not actually "mentally deficient" though otherwise in good health. It is to be noted that a large proportion of the children have "teeth in a state of advanced decay." The inquiry showed conclusively that "the most backward children in a school are also the worst fed." It should be mentioned that 130 of the 450 backward scholars "were also insufficiently clothed." When cold is added to ill-feeding or insufficient feeding the intellectual powers will not long be at their best. As to the causes of underfeeding they may be very various. Misfortune and genuine poverty in some cases, idleness and extravagance with drunkenness and wilful neglect in others, all come into the account and show how complex the problem is and how difficult, or rather how impossible, it will be to remedy the evil by one method only if the interests of the child and those of the taxpayer are to be equitably dealt with.

Our Cowsheds.

The annual report of the medical officer of health of the Lancaster rural district shows that notwithstanding the increased interest taken in sanitation there are conditions still to be found, without, indeed, the necessity for much searching, that are a disgrace as well as a danger to the community. From this district quantities of milk are sent daily to Manchester, Liverpool, and other towns, and the conditions under which the cows supplying it are kept become interesting. The report says that "the cowsheds are dirty, filthy places and very insanitary. Young stock are, as a rule, kept in dark, unwholesome dens which seem designed especially for spreading tuberculosis," and that "as the law stands the authority has very little power in the matter, as the cattle are not kept constantly in the cowsheds but are for about half the year turned out to graze"—happily for the poor beasts. There are seven sewerage systems in the district and not one is described as satisfactory, while in many parts of the district "there is an absence of suitable water-supplies." This, of course, renders more difficult than it should be the proper cleansing and scalding of dairy utensils. This sketch of the conditions at the source of the milk-supply in one locality may no doubt be taken as typical of the state of matters in many others.

Notification of Chicken-pox.

The town council of Heywood has sensibly ordered that for the next three months chicken-pox must be notified. This step has been taken in consequence of the prevalence of small-pox, incipient cases of which have been mistaken for chicken-pox. In his annual report just issued Mr. H. H. I. Hitchon, the medical officer of health of Heywood, states that no case of small-pox has occurred in a vaccinated person under 15 years of age.

A new infectious hospital will shortly be opened at Hyde and it will benefit to the extent of £869 under the will of the late Mrs. Booth of Godley.

April 25th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Swansea Hospital.

THE medical staff of the Swansea Hospital has for long been of opinion that some steps should be taken to prevent persons who are well able to pay a private practitioner from receiving treatment at the hospital. The house committee has been considering the question and has reported to the management committee that there is conclusive evidence of such abuse being practised and for the purpose of excluding persons who are not fit objects of charity it recommends that every proposed patient should fill up and send or bring with the subscriber's letter a form giving particulars of earnings, number of family, &c., and a declaration of inability to pay for private treatment, and, further, that any case which on the information supplied [illegible] should be referred to [illegible] eport, the house committee to decide after [illegible] is information whether the case is a suitable one. When the question of charging for medicines and dressings was under discussion the committee decided that it would be imprudent to make any charge.

Death of Dr. Edward Henry Warner.

Much regret is felt in Bristol on the occurrence of the death of Dr. E. H. Warner of Lawrence Hill. He was a native of Winchester and took the degrees of M.B , C.M. of the University of Edinburgh in 1883, shortly afterwards being appointed assistant medical officer of the county asylum at Lancaster, where he took part in the organisation and administration of the extensive additions which had just been made to that institution. In 1885 he took his M.D. degree and acted for a short time as one of the medical officers of the Bristol city asylum at Fishponds. During the past 18 years he had been in private practice, holding one of the Poor-law appointments under the Bristol board of guardians. He leaves a widow and one son.

The Midwives Act in Cardiff.

The administration of the Midwives Act in Cardiff is being very materially assisted by others than those who are officially concerned in its administration. A course of lectures to midwives was inaugurated by the University College last autumn and the local branch of the Queen Victoria's Jubilee Institute for Nurses has now established a maternity department. A house has been taken for the accommodation of a superintendent and eight midwives and for four pupils undergoing training. The cost of this new department is estimated at £400 yearly but it is expected that a large proportion of this sum will come back to the institute as pupils' and other fees.

Death of Mr John Jenkin Lloyd.

Mr. J. Jenkin Lloyd, who died suddenly from apoplexy at Llanelly, Carmarthenshire, was a native of that town and he had resided there for some years. He received his medical education at University College Hospital and after qualifying as L.R.C.P. Edin., L.S.A. in 1880 was for a short time engaged in colliery practice in Merthyr Tydvil. He was much interested in the public life of Llanelly and was a prominent member of the Presbyterian Church. His widow and one child survive him.

Bristol Eye Dispensary.

The annual meeting of the subscribers to this institution was held on April 18th. The medical report stated that during 1904 the patients numbered 2315, compared with 2268 in 1903. The financial statement showed that a small favourable balance remained at the end of the year.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Surgeons of Edinburgh.

THE fourth centenary celebration of the Royal College of Surgeons of Edinburgh will be held on July 19th, 20th, and 21st. The programme will be as follows. On Wednesday, July 19th, at 9.30 P.M., there will be a reception of Honorary Fellows elect by the President and Fellows in the Royal College of Surgeons (full evening dress). On Thursday, July 20th, at 10.30 A.M., the Honorary Fellows elect, Fellows, and guests will meet in Parliament Hall (academic robes, official costume, or uniform). At 11.30 A.M. there will be Divine Service in St. Giles's Cathedral, to which a procession will start from Parliament Hall at 11 A.M. At 4 P.M. in the M'Ewan Hall there will be an address by the President, presentation of congratulatory addresses, and conferring of Honorary Fellowships. The doors will be opened at 3 P.M. and there will be an organ recital at 3.30 P.M. (Honorary Fellows elect, Fellows, and guests will be expected to attend in their academic robes, official costume, or uniform). At 9.30 P.M. there will be an evening reception in the Royal College of Surgeons (full evening dress or uniform). On Friday, July 21st, at 3.30 P.M., there will be a reception in the grounds of George Heriot's Hospital. At 7 P.M. there will be a banquet in the Music Hall (court dress, uniform, or full evening dress). Dinner tickets for ordinary Fellows, one guinea. Except in the case of the reception on July 19th and the cathedral service admission to the various ceremonies will be by ticket only. Fellows of the College who desire to attend the celebration are requested to intimate the fact and state at which of the ceremonies it is their intention to be present. Letters to this effect, addressed to the honorary secretary, Fourth Centenary Celebration, Royal College of Surgeons, Edinburgh, must be received on or before June 1st. After that date it may not be impossible to guarantee tickets for the various functions.

University of Glasgow.

The difficulty which exists in the way of making alterations in the curricula of any of the Scotch Universities was emphasised recently at the monthly meeting of the Glasgow University Court. In the present state of matters independent reform or development, except in insignificant details, is almost impossible. According to Professor Jones, who raised the question in the University Court in the event of any proposed new ordinance they had to communicate with the Senate and the general council (which was quite right), but they had also to communicate with the other Scotch Universities and if they dissented they reported to His Majesty in Council. Then His Majesty in Council referred the question to the Universities' Committee. This committee in turn reported to His Majesty and the matter was then laid before both Houses of Parliament. It was pointed out that the Scotch Universities did not possess the same privileges as Manchester, Liverpool, or other universities such as Birmingham, in which such changes as were involved in these ordinances could be effected by the bodies themselves. Professor Jones formally moved "that we call attention to the difficulty of bringing about changes in the curricula, the arrangement of winter and summer sessions, and other matters, arising from the fact that such changes can be carried out only if the four Universities act together and that a committee be appointed to consider the question." After some discussion the motion was carried and a committee was appointed. There is no doubt that the decision of the court will commend itself to all interested in the welfare of the University. It seems intolerable that freedom of development in any one university should be restricted by the mere cumbrousness of the necessary procedure. Although a certain standard of uniformity for the four Universities is advisable it is surely not essential or to their advantage that they should always act together. The needs of the University of Glasgow, situated as it is in a centre of enormous industrial development, cannot always be the same as those of the University of Edinburgh or the University of Aberdeen.

The Glasgow and West of Scotland Coöperation of Trained Nurses.

The annual report of the Glasgow and West of Scotland Coöperation of Trained Nurses records a year of continued prosperity and useful work. Founded 12 years ago this association, as shown by the success with which it has met, has filled a distinct want in Glasgow and the West of Scotland. The convenience of such an association to the public and to the medical profession is obvious, as with so large a staff of nurses as it possesses it makes it extremely easy to secure a nurse for a sick person even on the shortest notice. Also the fact that no nurse is admitted to the staff unless she can produce a certificate of three years' continuous and systematic training in a recognised general hospital of at least 100 beds and that maternity nurses are not exempt from this condition guarantees that each nurse must have attained to a certain standard of efficiency. The value of such an association to the nurses themselves cannot be overrated. The nurse who after completing her hospital training determines to take up private nursing without joining some such association as this will almost invariably at first find cases difficult to get and even when a certain connexion has been formed the outlook is always more or less precarious. According to the report of this association the average amount earned by each nurse during the past year, allowing one month for holiday, was between £60 and £70. In 1894, when the coöperation was first started, the nurses on the staff numbered 31, the cases nursed numbered 65, and the gross earnings of the nurses were £293. In 1904 there were 176 nurses on the roll, 1762 cases were nursed, and the earnings for the year came to £10,724. The executive committee is composed of members of the medical profession, representatives of the nurses, a few business gentlemen, and several ladies interested in the work. With a committee composed in this fashion one can expect that the interests neither of the public or the medical profession nor of the nurses themselves will be neglected and that the association will be run on a sound financial basis.

April 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The General Medical Council and Ireland.

Dr. Leonard Kidd of Enniskillen has issued his address as a candidate for the office of Direct Representative on the General Medical Council at the coming election in 1906.

After pointing out that the seven Irish Representatives are at present drawn from the consultant class, are all resident in Dublin, and are all in some way connected with teaching centres, he asks for support on the ground that he is a "provincial general practitioner," absolutely unconnected with any medical school or corporation Dr Kidd is in favour of increasing the Direct Representation to the extent of one half of the Council and of election of the Direct Representatives under a topographical arrangement, of the 'one portal' system of examination, of a "Students' Register,' and of stringent measures being taken against unqualified practice Dr Kidd adds that should any more acceptable "provincial general practitioner' come forward as a candidate he is prepared to accept the decision of the electorate as expressed by a preliminary poll or other satisfactory means and retire in his favour Since Dr Kidd s [illegible] Irish Medical [illegible] the principle [illegible] agh, Donegal, Sligo, Roscommon, co Cork, Waterford, and South County Down The Portadown and West Down division of the British Medical Association has passed a similar resolution In the daily papers of April 25th a letter appears from Dr George F J Greene making the suggestion that since about nine months must elapse before the medical men of Ireland can elect one of their number to voice their views on the General Medical Council it would be unwise to make any promises of support until there is a full opportunity of considering the matter at a meeting of the medical electors in Dublin or elsewhere He says there is a general feeling that Dublin is much over represented Dr Greene is a well known practitioner, he has been a justice of the peace for the county of Wexford for many years and is a vice president of the Irish Medical Association.

Tragedy in an Asylum

In the Monaghan and Cavan Asylum on April 23rd, about 10 P M, when the patients in the institution were retiring, a quarrel took place between two female patients who have been 20 years in the asylum, during which one of them struck the other several blows with an enamelled vessel on the head, with the result that she died 20 minutes afterwards from compression of the brain An inquest was held on the next day, the jury finding that death was due to the injury done to the brain by the wounds to the head

Royal Victoria Hospital, Belfast

In the Belfast papers of April 19th an interesting extract has been published from a New Zealand paper, the *Lyttelton Times*, written by a medical man, Dr Thacker, who gives an account of his visits to hospitals at Dublin, Edinburgh, Belfast, New York, Chicago, and Baltimore He says the best and most up to date institution that he saw was the Royal Victoria Hospital Belfast, and he emphasises specially [illegible] plenum system of heating and [illegible] system by which each member [illegible] hospital of his own, the "unit' consisting of a large male and female ward of 14 beds each with two small wards Each "unit' has its own kitchen, each physician has a clinical laboratory and lecture room, and each surgeon an operating theatre The architect of the new hospital at Bombay, who went to Belfast personally to inquire into the plenum system, intends, as stated by Dr Thacker, to make provision for it in his plans

The Meath Hospital and County Dublin Infirmary

The annual meeting of the governors of the Meath Hospital took place on April 13th The report announced that the committee of the hospital has determined to erect a building for the nurses in the hospital grounds Plans for this block have been prepared and the cost will be about £5000 There was some discussion as to the question whether the representatives of the county council had a right to exercise a vote in the election of governors of the hospital, and an opinion was expressed by those representing the hospital authorities that they had not A meeting of the Dublin county council was held at the offices in Rutland square on April 20th when the chairman, Mr P J Neill, J P, alluding to the published report of the discussion at the Meath [illegible] should be made as to t [illegible] of the council on that [illegible] that in the case of a t [illegible] funds of that institution their representatives should not occupy an inferior position

PARIS.

(FROM OUR OWN CORRESPONDENT)

Gelatin in the Treatment of Aneurysm.

AT the meeting of the Academy of Medicine held on April 11th M Le Dentu reported a successful case of popliteal aneurysm treated by injections of gelatinised serum, a method which was introduced by M Lancereaux and M Paulesco Measures tending to occlude the artery such as ligature above the sac or extirpation of the sac, are in the case of a popliteal aneurysm, peculiarly prone to be followed by gangrene M Le Dentu s patient was a man aged 20 years, who suffered from a traumatic popliteal aneurysm During a period of two months he received seven injections of a serum containing 2 per cent of gelatin in quantities of 200 grammes at a time The injections were made in the gluteal region After the second injection the pulsation in the sac had disappeared and at the end of two months the cure was complete The method is simple and if care be taken to sterilise the gelatin by exposing it to a heat of 115°C so as to remove any risk of tetanus infection it may be said to be free from danger

Hygiene in the Laundry

A decree dealing with the above subject has just been issued by the Council of State, acting on instructions from the Minister of Commerce and of the Consultative Committee of Arts and Manufactures The decree lays down that no dirty linen shall be brought into the laundry except carefully packed in sacks or in some other receptacle which can be absolutely closed during transit If possible the dirty linen, together with its receptacle, must be disinfected before any sorting is done, or at least the linen must be wetted so as to avoid any dissemination of dust In this last case the receptacles must be scoured or disinfected separately Disinfection is obligatory in the case of dirty linen coming from hospitals or from any place where sick folk are received Finally, the staff employed in the manipulation of the linen are to be supplied with overalls which shall be kept specially for the work Dirty linen must not be handled in the ironing rooms or in any other room in which clean linen is handled and no article of food or drink is to be consumed in the rooms devoted to the handling of dirty linen

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

Meningitis decreasing in New York City

MENINGITIS with the coming of warmer and more settled weather, is on the wane in New York The death rate for the week ended April 8th at noon was 20 11 per 1000 while for the corresponding week of 1904 it was 25 76 During the week ended April 8th there were 110 deaths due to cerebro spinal meningitis compared to a death list of 131 in the previous week from the same cause It is also believed that several deaths have been ascribed to meningitis which were in fact due to other diseases [illegible] Association of Greater New [illegible] subjects discussed was that of [illegible] in the treatment of cerebro spinal meningitis Dr Arthur Wolff of the New York board of health described the results of his investigations as to the value of the serum as a remedial and curative agent He stated that his conclusions were that practically the only good the serum did was when it was applied in the earliest stages of the disease and then only when administered in large doses In the later stages he said that antitoxin was absolutely useless Dr Wolff said that experiments with white rats, rabbits, guinea pigs, and monkeys seemed to show that a certain antagonism existed between diphtheria antitoxin and the cerebro spinal meningitis cultures It had been noticed with the outbreak of meningitis that cultures taken from the nose and the throats of patients in the hospitals at the time of the abatement of the diphtheria epidemic showed highly different growths, leading to the supposition that the two diseases were antagonistic Acting on this supposition attempts had been made to use antitoxin in the treatment of cerebro spinal meningitis These as stated above, had been hopeless in advanced cases but often helpful in the early stages of the disease.

New York City Census by the Board of Health.

The New York board of health is at the present time taking a sanitary census, an appropriation by the board of estimate of $35,000 (£7000) having been made for this purpose. 150 medical men have been put to work on the census, whose duty will be to ascertain not only the exact population of the city, but to get an idea of the health of the entire community, according to age, nationality, and locality. Every person will be subjected to an examination and, as far as is possible, the cause of his or her condition recorded, together with the name, address, age, and if a foreigner his or her condition as near as can be ascertained on entering the United States, so as to show whether a disease was contracted here or imported. The work is expected to take four or five months, perhaps longer.

April 16th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Week's Record in Plague Mortality.

A RECORD of 53,895 deaths from plague throughout India was returned for the week ending March 25th. This is a rise of 11,807 over the previous seven days. It forms a lamentable sequel to the let-alone policy which has been formulated by the Government of India and adopted by the provincial governments. Of this large total 20,501 deaths occurred in the United Provinces, 18,778 in the Punjab, 8630 in Bengal, 2548 in the Bombay districts, 968 in Rajputana, 618 in Bombay City, 570 in Calcutta, and 95 in Rangoon. The outbreak in Aden seems to be dying down, as only 32 deaths were recorded. The disease is spreading not only in Rangoon itself but in other parts of Burmah.

The New Plague Research Committee.

The Government despatch concerning the further scientific investigation into the etiology of plague announces the appointment of a committee. It admits the failure of the expedients which have been tried and recognises that educated opinion is disposed to criticise the Government for its present policy of inaction. It expresses the opinion of the Government that the repressive policy first adopted was worse than useless and admits that because later the epidemic spread to parts where the enforcement of strict measures would be dangerous the policy of compulsion was deliberately replaced by one of persuasion and assistance. It, however, admits that the latter policy has been as much of a failure as the former one. After eight years of the pestilence the Government concludes that "we think that we should now deliberately attack the problem from the scientific side." It is better late than never, but the medical world will certainly charge the Government with neglect of the enormous opportunities which the continued presence of the disease in India has offered for its more exhaustive study. In making proposals for the constitution of the committee of two or three of the best experts available the Government half apologises to the Indian Medical Service. It ought to apologise because from this service a very competent committee might have been formed long ago and might have been carrying on original investigations under continuous conditions and with numerous other advantages. The committee is to have an absolutely free hand in the conduct of its inquiry. It is to be hoped that it will be free to report also. No term for its inquiries has been fixed "but so long as they are steadily increasing our stock of knowledge of a kind which may be expected in the end to lead to practical results we would place no term to the inquiry." It appears that on the recommendation of the Lister Institute and the Royal Society a small committee of these bodies with a representative of the India Office will administer a grant for the purpose of an Indian plague research expedition, consisting of two experts and two junior Indian medical officers. The joint committee is to prescribe and direct researches and to examine results. It seems strange that "two or three of the best experts available" should require to have their work prescribed and their researches directed.

Endowment for Sanitary Improvements.

Spontaneous gifts for sanitary improvements are so uncommon in India that the action of Raja Joyendra Narain Roy of Lalgola in the district of Murshidabad deserves to be brought to notice. He has given Rs.50,000 for the creation of an endowment for the sanitary improvement of the district as a memorial to his late wife. The Raja previously gave a lakh of rupees for improving the water-supply in the different districts of Bengal.

April 7th, 1905.

Obituary.

CALEB CAREY RICHARDS, M.D. ST. AND., M.R.C.S. ENG., L.S.A.

THE death, in his sixty-eighth year, of Dr. Caleb Carey Richards of Arundel-square, Islington, on April 19th, marks the severing of another link with the past generation of practitioners and the termination of a career conspicuous for its usefulness. Receiving his professional education at King's College, London, where he enjoyed the surgical tuition of Sir William Fergusson, he graduated as M.D. at the University of St. Andrews in 1861, also taking the diplomas of M.R.C.S. Eng. and L.S.A. in the same year. He then became assistant to Dr. Davies of Aberdare, a connexion by marriage. There he extended his knowledge of the surgical side of his profession and in January, 1866, contributed to THE LANCET a report of a case of hydatids of the liver, in which he advocated the use of operative measures as opposed to the medical treatment then in vogue. During that year there occurred a memorable outbreak of cholera in the East-end of London and he was placed in charge of one of the dispensaries which were organised to cope with the epidemic. Some idea of the arduous nature of the work may be gleaned from the perusal of an article from his pen which appeared in the *Medical Press and Circular* on Jan. 2nd, 1867, and in the course of which he stated that he had, in coöperation with three assistants, attended 7000 cases in six weeks. On the conclusion of the outbreak he obtained without solicitation and as the result of the admiration aroused by his devotion to duty a parish appointment vacant at that time in the district and here he practised uninterruptedly for 17 years, being compelled at length, on account of ill-health, to relinquish his extensive connexion. He had during this long period enjoyed an enormous popularity as an obstetrician, his attendances on labours reaching, in round numbers, the extraordinary total of 10,000; and his experience in this department of practice led to his receiving an appointment as assistant physician to the Royal Maternity Charity under the auspices of Dr. Robert Barnes. Dr. Richards leaves a widow and two sons, one of whom is in the medical profession.

ALEXANDER KEITH CAMPBELL, M.D. EDIN., D.P.H. ABERD.

Dr. A. Keith Campbell of The Lyncombes, Ebbw Vale, Monmouthshire, died on March 23rd, after a very brief illness, in his thirty-second year. This premature close of a career which was remarkably full of promise has come as a painful shock to a large circle of his attached friends. At the Universities of Edinburgh and Aberdeen, where he obtained his professional education, his work was characterised by unusual brilliance. At the University of Edinburgh eight class medals out of a possible ten fell to his lot. He was awarded honours on graduating as M.B. and C.M. in 1894, and commendation when he proceeded to the degree of M.D. in 1898; while the diploma of D.P.H. which he received at Aberdeen was also taken with honours. Dr. Campbell's earliest appointments were chiefly in asylums for the insane. Among his various contributions to the periodical literature of the profession, one on Recovery after Taking an Ounce of Chlorodyne and 250 Grains of Sulphonal was published in THE LANCET of March 6th, 1897, p. 661. Dr. Campbell was possessed of a kindly and tactful nature and his skilfulness in practical work inspired confidence and esteem in all with whom he came in contact.

TIVERTON INFIRMARY.—The trustees of the late Mr. Stephen Henry Fisher, L.R.C.P. Lond., M.R.C.S. Eng., have presented a valuable library of medical books to the Tiverton (Devon) Infirmary.

son a
Tyne.

Elementary Anatomy and Biology.—Ronald Mathwin Angus, Harriett Amelia Rachel Ap
Bower, John George Campb
Cooper, College of Medicine,
Evans, Guy's Hospital; Franc
pital; Reginald Cyril Herbert
Gray, Arthur Charles Greene, John Pritt Jackson

Wood, and Alfred Armitage Woodhouse, B.A., College of Medicine, Newcastle-upon Tyne.

Chemistry and Physics.—Jacques Marius Louis François Coquelin,
cival Rivers Harvey, London
Hughes and Stanley Larmond
Lennox Macdonald Stewart,
College, London.

SECOND EXAMINATION.

Anatomy, Physiology, and Materia Medica.—Second class Honours: Charlotte Purnell and Elizabeth Patteson, London School of
ude Ethel O'Brien, College of
Pass List: Helen Young Camp-
Women; Herbert Ridley Crisp.
Edmeades, Helen Mary Gurney,
David Ewart Johnstone, College
Tyne; Thomas Davidson Miller, M
Hospital; Hubert Shield, College
Tyne; Herbert James Slade, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; and Edward Davison Smith and John Franklin Young, College of Medicine, Newcastle-upon-Tyne.

THIRD EXAMINATION.

Orrock Arnott, College of Medicine, Newcastle-upon-Tyne, Thomas Henry Bishop, M.R.C.S., L.R.C.P., Edinburgh University and College of Medicine, Newcastle-upon-Tyne; Sydney Havelock, B.Sc., College of Medicine, Newcastle-upon-Tyne; Thomas Davidson Miller, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Hector Graham Gordon Mackenzie, M.A., College of Medicine, Newcastle-upon Tyne; Bertha Mary Mules, London School of Medicine for Women; Jessie Jean Martin Morton, Edinburgh School of Medicine for Women; Roland Wilfred Pearson, M.R.C.S., L.R.C.P., London Hospital; Howard Bewlay Stephenson, College of Medicine, Newcastle-upon-Tyne; Herbert James Slade, M.R.C.S., L.R.C.P.
; Arthur John Turner,
, Birmingham University;
bert Rex Wilkins, College

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April meetings of the examiners held in Glasgow the following candidates passed the respective examinations :—

First Examination (Five
James Denis Collins Ca

Killevock, co. Tyrone.

James Logan, Glasgow; Peter Jo
Zealand; Thomas Urmiston Wilson
Milne, Glasgow; Henry Gilbert
Fitzgerald Anderson, Scotland;
Bombay; Owen T. Jones, Bangor;

rse).—Jesudasan S. Lamech,
rton, Buteshire.
n Haltby, Belfast (with dis-
William Frederick F. Durr,
uncan Edinburgh; Charles

North Berwick,
Ashurst, Bedford
Glasgow; Gavin Watson Hill, Lesmahagow; Arnold M'Millan, Belfast; John Theodore Anderson, Victoria, and William Turner

seven in Midwifery, and eight in Medical Jurisprudence.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates having passed the necessary examination have been admitted Fellows of the College :—

S. S. Pringle, M.B., B.Ch., University of Dublin, Surgeon to Mercer's Hospital, and W. I. de Courcy Wheeler, M.D., B.Ch., University of Dublin, Surgeon to Mercer's Hospital.

MEDICAL MAGISTRATE.—Mr. George Jackson, F.R.C.S., honorary surgeon to the Plymouth Public Dispensary and to the Devon and Cornwall Ear and Throat Hospital and one of the Direct Representatives of the profession on the General Medical Council, has been placed upon the commission of the peace for the borough of Plymouth.

OLD CLOTHES AND CHOLERA: RUSSIAN PRECAUTIONS.—In view of the anticipated cholera epidemic in St. Petersburg dealers in second-hand clothes will be obliged to hand over their merchandise to the city disinfecting rooms and the report is added that on the first appearance of cholera trade in so-called "old clothes" will be suppressed until the complete disappearance of the epidemic.

LIÉGE EXHIBITION.—The Universal Exhibition to be held at Liége this year bids fair to be one of considerable interest and on and after May 1st the service by the Harwich route between London and Liége will be greatly accelerated. Passengers leaving Liverpool-street Station at 8 40 P.M. will be due at Liége at noon the following day, while dining and breakfast cars will be attached to the boat trains between Liverpool-street Station and Parkeston Quay, Harwich, so that passengers may sleep and breakfast on the steamer before landing at Antwerp. Through carriages will run from alongside the steamer to Liége and *vice-versâ*, but none of our readers will be well advised in their anxiety to make a through journey to miss the opportunity of seeing Antwerp and Brussels.

RUSSIAN MEDICAL EXAMINATIONS: SCARCITY OF CANDIDATES.—The medical examination committee of the University of Moscow began its work in the second week of April in Moscow. There were only two candidates for examination, the one a lady doctor who had obtained her education abroad and the other a male doctor from a foreign university. The examination of these two people, says the *Novoe Vremya*, costs the University £200 and the two candidates contribute only £2 in the form of fees.

THE MEDICAL GOLF TOURNAMENT.—The medical golf tournament for 1905 will be held on Thursday, May 25th, at Sunningdale by the kind permission of the Sunningdale Golf Club whose links adjoin the station. The regulations for the competition are as follows: 18 holes match play *v.* Bogey. Class I., handicaps of 12 and under. Class II., handicaps of more than 12 (24 limit). Members of Sunningdale Golf Club deduct 2 from their handicap. No match may start later than 3 P.M. and no previous play will be allowed on the day of the tournament. There will be three prizes in each class: first and second prize, and prize for best last 9 holes *v.* Bogey, and there will be a foursome sweepstake competition *v.* Bogey in the afternoon. Players are left to arrange their own matches or can apply to the honorary secretary of the tournament, stating the time that they wish to play. A green fee must be paid on the day to the steward at Sunningdale. Entries, stating lowest handicap and inclosing 5*s.* entry fee, to be made on or before Wednesday, May 24th, to the honorary secretary, Mr. Rolf Creasy, Windlesham, Surrey.

LUNACY INQUIRY.—An inquiry was held at Lancaster recently by Mr. T. H. Fischer, K.C., Master in Lunacy, assisted by a special jury of 23, the point at issue being the ability or otherwise of a lady of means to manage her affairs. It was alleged that the respondent suffered from the delusion, amongst others, that certain people were her relatives and that in consequence these persons had an undue influence over her actions. Mr. G. W. Mould, formerly medical superintendent of the Cheadle *Asylum, said that from his interview with the respondent he* was convinced that she did not understand the nature of the property she possessed nor how it was invested and was of unsound mind and unable to manage her affairs or herself. He gave particulars of several delusions relating to her imaginary relatives, from which it appeared that she believed that when five years old she was married to three husbands and had had children by them. She had also stated that her father married the Queen of Morocco and she had other delusions which the witness described as "fixed and persistent but varying in intensity." Dr. D. M. Cassidy, medical superintendent of the County Asylum at Lancaster, agreed with the conclusions of Mr. Mould. He had gone through several account books with the respondent and found that she could not balance them. She repeated the story of the three supposed husbands to him, adding that she believed the first to have been the Amir of Afghanistan. For the respondent Dr. E. S Reynolds, visiting physician to the Manchester Workhouse Infirmary, alleged that though the lady undoubtedly had delusions she gave reasonable answers to his questions about money. So far as he was able to see they had no effect upon her conduct save the frequent gifts to the supposed relatives. The jury found that the lady was incapable of managing her affairs but capable of managing herself.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

London County Council and the Insane.

SIR JOHN BATTY TUKE has the support of Mr. JOHN BURNS and Mr. BENN in bringing in his Bill to authorise the London County Council to provide receiving houses for the reception of persons mentally afflicted or alleged to be of unsound mind and to authorise the detention of such persons in these houses.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 19TH.

Nursing in Ireland.

Dr. E. C. THOMPSON asked the Chief Secretary for Ireland whether he was aware that, by the arrangements enforced by the Local Government Board for Ireland in its nursing circulars, the Irish county hospitals were not recognised as training schools and nurses trained in these institutions were debarred from occupying the position of charge nurses for district hospitals; and whether, in view of the experience of leading physicians and surgeons in this matter and of the fact that nurses so trained were recognised as trained nurses in Great Britain and by the English Local Government Board, he would take steps to abrogate the rule in Ireland.—Mr. LONG answered: Many of the Irish county hospitals are recognised as training schools for nurses and the Local Government Board regards as "qualified nurses" persons who have obtained certificates of proficiency from these institutions In order to encourage the appointment of at least one qualified nurse in each Irish workhouse it is provided by Section 58 of the Local Government Act of 1898 that one-half of the salary of such nurse shall be recouped from the local taxation account; and to insure that none but nurses of high qualifications should obtain these appointments the Board only recognises the certificates of general, clinical, or other hospitals where there are a good teaching staff and a large number of beds available for instruction. The present arrangement has been found to work satisfactorily and has received the approval of the medical profession generally.

Dr. THOMPSON further asked the Chief Secretary for Ireland whether he would lay upon the table of the House the report of the medical inspector of the Local Government Board as to the capabilities of the Tyrone county hospitals for training nurses.—Mr. LONG said: Such reports are confidential documents intended for the information of the Board and it would be contrary to the invariable practice to make them public.

Infantile Mortality.

Dr. THOMPSON asked the President of the Local Government Board whether he was aware of the percentage of deaths of infants; whether he received tabulated records of the deaths in different urban and rural districts; and whether in future he would direct a medical inspector to visit such localities and inquire into the causes producing such results.—Mr. GE[illegible] replied: The Local Government Board is aware of the [illegible] infants in different parts of England and Wales. [illegible] this subject is derived from particulars given in the weekly and quarterly reports of the Registrar-General as to certain towns and from the annual reports of medical officers of health of urban and rural districts, copies of which are sent to the Board. I could not undertake to direct a medical inspector to visit every locality in which there is a high rate of infantile mortality, but where this is the case the circumstance is taken into account with other considerations in determining whether there should be a medical inspection of the district.

Irish Schedule of Infectious Diseases.

Dr. THOMPSON asked the Chief Secretary of Ireland why the Local Government Board for Ireland had omitted measles from the schedule of infectious diseases in view of the character of this disease.—Mr. LONG replied: The infectious diseases to which the Infectious Disease (Notification) Act, 1889, applies are specified in Section 6 of the Act and do not include measles. Power is, however, given to the sanitary authority by Section 7 to order, subject to the Board's approval, that the Act shall apply in its district, permanently or temporarily, to measles or any other infectious disease not mentioned in the Act.

SIBBALD.—On April [illegible] burgh, Sir John Sibbald, M.D., F. [illegible] in Lunacy for Scotland, aged 72 years.

STOTT.—On the 26th inst., at Deansgrove, Haslingden, William John Stott, M.D., M.R.C.P. Interment, Monday next at Haslingden Parish Church.

Notes, Short Comments, and Answers to Correspondents.

DAMMING OF THE THAMES.

To the Editors of THE LANCET.

SIRS,—The objections which are now coming to light after many months of discussion are assuming a form bordering on the ridiculous. Does your correspondent Dr. Stanley Haynes seriously believe that the vertical displacement of the air above the river by the rising tide is of the slightest hygienic value or is he joking? The rise of the tide will—in six hours—displace its own bulk of air, of course, but a very slight breeze will displace in five minutes more air than the tide can move in five days, and when the tide is down we get the intolerable stench of the mudbanks for several hours to poison the air and the rising tide lifts this foul air to pour out over the riparian districts.

There are no "low banks on the Surrey side" to be overflowed. Perhaps he refers to low-lying lands. If so, these will be pumped drier than they ever are now and so improve the health conditions. Then he says that none of the water-supply of London should be drawn from the Thames. But two thirds of the water-supply is now so obtained and it is one of the best and purest services in England. Perhaps, however, he means that the supply should not be taken from the river below Teddington. It will not be necessary to do so as the returns show that there is sufficient—at least for 50 years—above Teddington, but the appended letter from a great Thames chemist of 40 years' standing ought to satisfy any scruples on this question of the condition of the river.

I am, Sirs, yours faithfully,
T. W. BARBER.

Tothill street, Westminster, S.W., April 18th, 1905.

*** Mr. T. W. Barber's words must carry great weight. The opinion of the chemist in the appended letter appears to be that the scheme of converting the river above Gravesend into a fresh-water lake "would effect an enormous improvement in every way." Upon this opinion, however, he places the important reservation that he is not quite clear "that the present method of obtaining and discharging the effluent from the works at Barking creek and Crossness would under the new circumstances be the best."—ED. L.

CAISSON DISEASE.

IN its engineering supplement the *Times* of April 19th mentions that the Dutch Government is understood to be contemplating legislation in connexion with the risks of those working in compressed air. The same journal was recently informed from Newcastle that a workman had brought an unsuccessful action against the Cleveland Bridge Company, Limited, claiming damages for illness attributed to the compressed air in a caisson chamber in which he had been employed. Good results are said to have been obtained in the treatment of caisson disease by a temporary course of air under considerable pressure, the gradual reduction of which invariably restores the patient to the full possession of his normal faculties.

DIFFICULTIES UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—Would you kindly state what you think is the generally accepted ethics in the following circumstances?

I am acting as a "locum tenens" here and in the ordinary course of business saw in my consulting room a man who is a clerk at a railway station and who had been sent out of the office by the superintendent because the other clerks said that he had small-pox and refused to work with him. After carefully examining the patient I came to the conclusion that it was a case of chicken pox. The rash was very like small pox but with the face scarcely touched. However, after he got home the people in the house were scared and I was sent for. Meeting another professional man I took him with me. He said that he should notify it as small-pox. However, I felt sure of my diagnosis; but on the advice of my *confrère*, and as I was only a "locum" and did not want to run the slightest risk of injuring the gentleman I was acting for, I compromised and sent a polite note to the medical officer of health narrating the circumstances and asking him if he would kindly see the case and state his opinion. To this I received, much to my astonishment, a reply [illegible] it was no part of his [illegible] that if I thought it w[illegible] diagnose it I had better call in a practitioner who could.

I am, Sirs, yours faithfully,
THOMAS MARSHALL.

Bromley by Bow, April 21st, 1905.

*** We only express our opinion upon the facts as given to us by our correspondent. If, as our correspondent suggests, being in a position of difficulty he appealed to the medical officer of health for assistance and received the curt reply that he has quoted we have no hesitation in saying that the medical officer of health was wrong—ethically wrong in his attitude towards a medical colleague, and practically wrong as his action did not conduce to satisfactory public business.

It is an unfortunate fact that under the Infectious Diseases (Notification) Act difficulties may arise between the medical officer of health and the private practitioner owing to a certain position of superintendence which the medical officer of health possesses in the matter of infectious disease. We have always in THE LANCET urged upon both the medical officer of health and the private practitioner to work hand-in-hand for the good of the public. Such an attitude as that said to have been taken up by the medical officer of health in the above statement is, in our opinion, the exact converse to what is desirable.—ED. L.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—Will you be so kind as to give me your advice in the following case:—A calls B into consultation over case C. B recommends a certain line of treatment, A falls ill, and C having no confidence in A's assistant asks B to attend him. B agrees to do so on the distinct understanding that if A recovers before C, he (B) will hand the case over to A. A recovers and B writes to him placing the matter in his (A's) hands, stating at the same time that C is almost recovered. A replies that in the circumstances B had better finish the case. At the termination of the case C expresses himself extremely pleased with B's skill and states that in the future he will call in B should he or his family require any attendance. B says that he cannot agree to that as he owes his introduction to them through being called in by A as a consultant. C and his family express in strong terms their right to call in any medical man they wish.

Is B justified in attending C or his family in the future?

I am, Sirs, yours faithfully,

April 16th, 1905. ETHICS.

⁂ The situation is a most unfortunate one, because it inevitably brings the practice of inviting a fellow practitioner to a consultation into disrepute, and this practice is a very valuable one for the public. But members of the public have the *right* to choose their own medical man and, therefore, B is justified in attending C and C's family. B has conformed to ethics by refusing to do so previously, but if C will take no denial there is no other way out of the dilemma. —ED. L.

MILEAGE OF THE LANCET.

A CURIOUS correspondent informs us that he estimates that in THE LANCET for 1904 there were about 600,000 lines, or 6,000,000 words, or about 30 miles of type, in the body of the paper, excluding advertisements. He thinks perhaps the Editors do not know the mileage over which their eyes have to travel in the course of a year. We certainly did not and are interested to know and as our readers may be interested to know also we insert this note.

MANNERS IN THE LONDON STREETS.

To the Editors of THE LANCET.

SIRS,—With reference to your recent annotation on this subject it is clear that however careful is the attempt to protect young girls from degrading influences the task is hopeless as long as men allow their unbridled tongues to utter the coarse language which pollutes much of the intercourse of the day. But it must be remembered that the modern craving for excitement is responsible for much of the deterioration which the female mind must suffer from contact with the highly emotional situations in which they are placed. Attendance at race meetings can never be unaccompanied by any but the very worst influences, while the language that may be there heard is worse than usually prevails in the streets. Just as the wine-bibbing proclivities of our ancestors have reacted to a considerable extent in the growth of moderation to-day, so it is possible that the fashion and the craze for excitement and self-enjoyment which so blatantly obtrude themselves in selfish prodigality will also react on the succeeding generation which, seeing and suffering from the folly of its forebears, recognises that its well-being and its happiness lie in the direction of an ordered self-restraint.

I am, Sirs, yours faithfully,

April 24th, 1905. M.D.

A CONDITIONAL BEQUEST.

Mr. Robert Wallace Murray, J.P., of Ennikeen, Newcastle, co. Down, who died on Christmas Eve, 1904, and whose will has just been proved in the district registry of Belfast, left, amongst other legacies, £1000 to the Hospital for Sick Children, Queen-street, Belfast, and £1000 to the Society in Belfast for Providing Nurses for the Sick Poor. As to the residue of his estate, which is expected to be large, the testator directed that it should be held by his trustees upon trust to divide the same into two equal shares, one to be paid to the London Missionary Society, whilst as to the other his trustees should "as soon as possible intimate to the governors of the Forster Green Consumptive Hospital, Belfast, what the said half consists of and how it is then invested, and what the trustees estimate the net annual minimum income thereof will be, and if the said governors should within 12 months from the date of receiving such intimation satisfy the trustees that they can from outside sources provide proper accommodation in addition to their then accommodation for as many patients as such net annual minimum income will support, allowing £1 per week for each patient, then the said trustees shall be at liberty to agree with the said governors that on such additional accommodation being provided within two years from that date they will settle a scheme under which the entire income of such share and any accumulations thereof shall be applied in the maintenance in the said hospital of consumptive patients who are unable themselves to pay any portion of the cost of their maintenance and treatment." In the event of the failure of the governors of the hospital to comply with the foregoing conditions the testator empowers his trustees to apply the income "for the maintenance and treatment, in hospitals, of consumptive patients in such manner and form and subject to such rules and conditions as the said trustees may from time to time determine."

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your issue of April 8th, p. 929, col. 2, line 30, "the uræmia being more marked" should read "the anæmia being more marked."

I am, Sirs, yours faithfully,

Blackburn, April 19th, 1905. J. W. MILLER.

◆

Londoner.—Such a notice can be sent by either the transferer or the transferee, but care must be taken that it is sent only to patients whose names appear upon the transferer's books.

B.O. Advocate.—We do not think that a plea in our columns for such a purpose would lead to any practical result.

Jas.—We have frequently published similar instances and have recommended the course that has been adopted.

R. G.—The other medical man should be informed of all the circumstances.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

---

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4

A Clinical Lecture

ON

SOME OLD AND NEW REMEDIES.

Delivered at the Liverpool Royal Southern Hospital on March 6th, 1905,

By WILLIAM CARTER, M.D., LL.B. Lond., F.R.C.P. Lond.,

PHYSICIAN TO THE HOSPITAL AND PROFESSOR OF THERAPEUTICS AT THE UNIVERSITY OF LIVERPOOL.

Gentlemen,—A short time ago I read before the Liverpool Medical Institution a paper entitled "Notes on Old and New Remedies." I propose to continue the subject to-day, illustrating my remarks by reference to cases, most of which you are acquainted with from having watched them within the hospital.

Oil of turpentine is a very old remedy and adrenalin is a very young one and one which, owing perhaps largely to its youth, has a loud voice which it makes extensively heard. Both claim to be powerful vascular astringents and each is often, though neither always, very useful. A case or two will illustrate this statement.

Case 1.—The patient, a man, aged 40 years, was admitted to hospital on Dec. 1st, 1904, with all the signs of extensive left pleural effusion. I saw him immediately after admission and directed that the pleural cavity should be at once aspirated, the skin over the left side of the chest to be then painted with a 10 per cent. solution of oleate of mercury in oleic acid, iodide of potassium to be administered three times daily, and a dry diet to be given. 102 ounces of a very deeply blood-stained fluid were drawn off. The colour was bright and the fluid was opaque to light, but on standing threw down a deep layer of corpuscles below a clear serum. Adrenalin solution, 1 in 1000, was injected immediately after the tapping. In 13 days reaccumulation had occurred and 115 ounces of an exactly similar fluid were withdrawn and adrenalin solution was again injected. After eight days further 108 ounces were withdrawn, followed as before by the immediate introduction of adrenalin solution. Shortly afterwards I called my colleagues into consultation and especially requested their opinion as to the advisability of resecting portions of one or more ribs with the view of bringing about contact between the visceral and parietal pleuræ. They were opposed to the proceeding on the ground that the large amount of blood pointed probably to malignant disease. I then prescribed ten minims of oil of turpentine three times a day in capsules, which I had hesitated to do previously, as a considerable amount of albumin was present in the urine. The reaccumulation which appeared to be commencing was checked and a fortnight later on introducing a fine explorer I failed to obtain any liquid. The man, as you see, is now fairly well, with a slightly contracted left chest. If the oil of turpentine did not check the reaccumulation, which the adrenalin solution had three times failed to influence, I do not know to what the result is due.

A curious circumstance occurred earlier in the year which also pointed to the inefficacy of adrenalin under certain very special conditions.

Case 2.—A patient, aged 34 years, was admitted on Feb. 6th suffering from stricture of the pylorus and the singular fact was that a fungating freely bleeding growth from the gum at the site of the upper left canine tooth was entirely uninfluenced by the application to it of a solution of adrenalin (1 in 1000) for a week; but all bleeding ceased immediately after the operation of gastro-enterostomy had been performed by Dr. W. Alexander and did not again occur during the further residence in hospital of the patient. He was operated on on March 23rd, 1904, and has been well ever since. Probably no hæmostatic would have had any effect.

Turning to another old remedy and its uses I wish to draw your attention to the fact that besides a considerable number of preparations, the effect of which when applied to the skin is to produce more or less severe irritation, the British Pharmacopœia in this the beginning of the twentieth century of the Christian era, and I do not know what period of advanced scientific enlightenment, contains at least six others which cause blisters wherever they are locally applied and which, therefore, are presumably designed to produce this effect, as they seem incapable of causing any other, at least any other that is not injurious. But is it possible that anybody to day believes in the utility of blisters? A few years ago when ordering one to be applied over an acutely distended and painful rheumatically inflamed knee-joint in a negro I was confronted by one of the students with a passage from a text-book on the practice of medicine which he was studying. In it their application was strongly discredited and I was asked in a becoming manner by the student which teacher he was to follow. My reply was that he ought not slavishly to follow either but to carry out the purpose for which I supposed he had come to us—viz., to observe for himself the effect of what was ordered; and if in that particular instance it should prove to do nothing more than add the pain of a blister to the severe pain of the rheumatic inflammation and effusion he would know what conclusion to come to. This advice was followed and he heard from the patient shortly afterwards that much relief to pain, instead of exaggeration of it, had followed the use of the blister, and he saw for himself so considerable a reduction of the swelling that for that case, at any rate, he was convinced of the utility of the practice. That is the kind of proof that commends itself most strongly to my mind. Gentlemen may give me any number of scientific reasons why in the nature of things a given result ought not to follow a certain course of action, yet I am driven to conclude that they and not the nature of things must be wrong if, in spite of what they say, I see that it actually does follow. And not only is this the case with regard to the *fact* of the application of a blister but equally as to the site where the application is to be made. In the negro it was applied directly over the inflamed knee-joint. Yet we are told that even if a blister can ever be supposed to do good it must on no account be applied very near to the inflamed part or it may increase instead of diminish the inflammation and thus do harm instead of good. "As a matter of practice, for instance, the rule is usually insisted upon that in a case of pericarditis the blister should not be put immediately over the pericardium but at some little distance from it." These are the words used by the author of one of the most popular books of to-day on the action of medicines and with them fully in my mind I ordered a large blister to be put directly over the pericardium in the case now to be mentioned which some, if not all, of you have seen, just as I ordered one to be applied directly over the knee-joint in the last.

Case 3.—A young woman, aged 18 years, was admitted on Feb. 1st suffering from not very severe rheumatic inflammation of the wrists and with probably a small amount of pericardial effusion. On the day but one afterwards, while still taking the salicylate of sodium ordered by Dr. F. H. Salisbury before my visits, she became alarmingly ill—blue, breathless, with quick, feeble pulse—and as though she might not live throughout the day. The cause of this change was a very large and somewhat acute increase in the pericardial effusion and I sent a message to the only one of my surgical colleagues who happened then to be in the hospital to ask him to come to draw off some of the fluid. He came, recognised the extreme gravity of the girl's condition, but considered that paracentesis pericardii involved too much risk to admit of its being undertaken. The patient had extraordinarily large breasts which nearly met in the middle line and probably obscured the usual landmarks relied on in making the puncture. A large blister was therefore at once applied over the increased area of dulness. Its early effect seemed to be to rouse the poor girl from the condition of semi-lethargy into which she had sunk. Next day a to-and-fro rub was audible over the base and this descended day by day till it involved the entire cardiac area. For some days now she has been free from all danger, the apex beat being felt in the normal position when the huge breast is raised and nothing but the possible inconvenience of an adherent pericardium being left. That this

after life by crippling the

ring with the heart's nutri-

to admit but all risk of

over. I wish to make two

observations by way of caution. The application of so large a blister was followed, as it not infrequently is, by some amount of strangury and traces of blood in the urine, which were, however, soon subdued by making the patient drink freely of alum whey made by boiling a pint of milk with a teaspoonful of powdered alum and straining away the curd. I also left directions that if any further blistering should be thought necessary the surface of the blister should be dusted with powdered camphor before application. Both of these methods you will find practically advantageous. Perhaps it was fortunate for the patient that the pericardial fluid was not withdrawn, as it is just possible that I might have been tempted, by a fear of a recurrence of her extremely perilous condition and by the apparent harmlessness of adrenalin in Case 1, to inject a little into the pericardium. But this, I must warn you, is a much more serious matter than injecting it into the pleural cavity, and if ever you sanction it you should be present to watch results so as to be ready promptly to counteract any injurious effects.

To turn now to some other remedies. Morphine is an old one, while pilocarpine is a comparatively new one. Both are of great use, both contract the pupils, but not infrequently there seems to be rivalry between them. The circumstances that may, in my opinion, occasionally render it advisable to select one rather than the other will be obvious from a case or two which I will relate.

CASE 4.—This case was that of a youth, aged 17 years, suffering from uræmic convulsions of the severest character, whom I saw with Dr. J. B. Edis on the afternoon of Feb. 23rd, 1905. The patient had had violent general convulsions at 3 P.M., at 3 5 P.M., and at 3.10 P.M. The tongue was bitten and the mind was so clouded that he could not understand anything which we said, as for example, that he should put out his tongue. He was extremely restless and so dropsical that the eyes were largely closed by œdema and it was with not a little difficulty that we were able to raise the upper lids enough to see that both pupils were widely dilated. The question put to me was whether it would be advisable to inject pilocarpine hypodermically, this substance being in readiness for the purpose. My strong advice, which was at once agreed to, was not to do this but to inject morphine instead. Before this could be done, however, another general convulsion occurred. A quarter of a grain of morphine hydrochloride was then introduced beneath the skin of the right forearm, while a messenger was sent for oxygen. There had been four fits in 20 minutes before the morphine was injected. 24 minutes then elapsed before another occurred. This, like the one attack which I had previously witnessed, was ushered in with wide dilatation of the pupils, a dilatation which under the influence of the morphine had for a time become much diminished. Again a quarter of a grain was injected. I was then obliged to leave but Dr. Edis kindly promised to keep me acquainted with the subsequent course of the case, which was that oxygen was procured shortly after the second injection, and its inhalation was at once commenced; that the intervals between the attacks became longer and longer until 9 40 P.M. when they ceased entirely. Now every part of this practice, both positive and negative, has been strongly condemned by some whose knowledge should entitle them to respect. Morphine is often said to be bad, pilocarpine to be good, and oxygen to be useless, and in some cases each one of these propositions would be true while in others they would as certainly be false, and your business here is to learn to discriminate between such of them as require opposite treatment though the disease may be called by the same name. One of the greatest banes of medicine is the elevation of the *obiter dicta*—for they are often nothing more, the mere chance expressions of men with a name concerning individual cases—into axioms supposed to be applicable to all, a bad kind of reasoning often followed by bad results. Such are those just mentioned—*dicta* uttered not surely on clinical but on what is termed scientific evidence. To take the last practice first. "In normal respiration the hæmoglobin of the arterial blood is practically saturated with oxygen, and can you hope to get more than saturation?" To this question, triumphantly propounded as if merely to ask it is to settle the entire subject in dispute, it might fairly be answered, if any answer were necessary, that oxygen exists in solution in the blood as well as in chemical combination and that whereas in ordinary respiration only 0·6 per cent. is dissolved, when pure oxygen is breathed this 0·6 rises to 3 per cent., or is multiplied five times; and when we consider that only 6 per cent. of the combined oxygen is ever used (for venous blood contains two-thirds of the 18·6 per cent. found in arterial blood) and that by administering the gas in a pure state we obtain nearly half as much again of readily available oxygen in solution as the entire amount capable of being utilised in ordinary conditions, we are surely entitled to ask if this may not be an advantage. But I must confess that I am content to rest the practice on a simpler basis than this and to point to the general convulsions, which recurred with the most alarming frequency up to the time of commencing the inhalation, and ceased to recur soon after it had been fairly established. I could not, of course, obtain frequent samples of urine for examination in the case under consideration. The small quantity which I did procure was acid, of specific gravity 1023, contained a very large amount of albumin, and microscopically presented numerous blood and other casts. But in a very similar case which occurred a few years ago in hospital, where the patient, a young woman, aged 18 years, was admitted in the status epilepticus and had frequent convulsive attacks with no intervening consciousness, we were able to procure the urine first by catheter and subsequently in the ordinary way and to prove that the specimen first examined, while its specific gravity was 1026, gave only 4·5 grains of urea to the fluid ounce, whereas that which was passed on the following day after the convulsions had ceased had a *lower* specific gravity (1020) but a much higher proportion of urea, as if the oxygen which was freely administered had caused the oxidation of poisonous nitrogenous products to the final term of harmless urea. The same diminution and final cessation of convulsions followed the oxygen as in the case which I have just related to you, but there was one marked difference between the two cases. This young woman's pupils were markedly contracted, while those of the youth were widely dilated, and I do not suppose that anyone would be foolish enough to inject morphine hypodermically when some unknown poisons were producing certain of the most marked effects caused by that drug. The young woman, like the young man, got perfectly well but neither would have done so if part of the practice applied to the one had been applied to the other. In the case of the young woman, some of the gentlemen around the bed, in reply to my question as to what could be done, suggested the hypodermic injection of pilocarpine. In both cases I think, for reasons which I shall give to you, this proceeding would have caused the patient's death.

But can anything be said in defence of using morphine? Yes, this—viz., that it seems rational to combat an unknown poison which widely dilates the pupils and causes general convulsions by employing one of the most powerful antagonisers of these symptoms. Then why not use pilocarpine, which, as everybody knows, antagonises atropine all along the line and might therefore have been expected to antagonise this unknown atropine-like poison which was doing all the mischief, the drug being at the same time credited with the power of eliminating urea and toxic products through the skin? If it did this and nothing more it would do no harm, even if it did no good. Urea is harmless and to get rid of it is of little advantage. But the reason for not using it is that the profuse outpouring of tracheal and bronchial, as well as salivary, secretion which pilocarpine invariably causes (and that even before the sweating which follows its use) may, and I believe does, kill patients where this outpouring occurs in those of them whose sensibilities are so blunted as to render them but little conscious of what is going on. If they are wide awake with all their senses acutely alive there can be no objection to its employment, but in such cases as those which I have mentioned it would be fatal. I do not suppose anyone would have been injudicious enough to inject morphine in the case of the young woman where the pupils were already contracted, while it would do nothing but good in the case of the youth and in all such cases, and pilocarpine would do harm in both alike. I am the more desirous of putting you on your guard in this matter because in my opinion the directions given with regard to the treatment of uræmia in some of the best modern treatises on the practice of medicine are dangerously loose and unguarded instead of being fenced about, as they should be, with strict limitations. I will not mention names, for authority in such matters should be subordinated to common-sense, but I will quote the very words of some justly esteemed recent books. Thus in one I read that "in uræmic coma sweating should be promoted by the use of pilocarpine or the hot bath"—the very condition of all others where pilocarpine should not be used. In a second we are told that "should the skin fail to respond ...... as in uræmia, pilocarpine (gr. $\frac{1}{8}$ to $\frac{1}{4}$) should be injected, after which it will continue to pour out on the application of heat," without a single word being said as to the circumstances—the existence, for example, of coma, which would render the practice dangerous. A third and still more recent book says in the same loose and unguarded way that "the removal of toxic products from the body makes it"—i.e., pilocarpine—"useful in uræmia."

Incidentally Case 4 seems also to dispose of one or two of those calmly dogmatic assertions to which we are apt to be treated, assertions which are probably received so deferentially because of the quiet assurance with which they are uttered, but which are often proved to be unfounded or at most to be only partially true as soon as a little rational scepticism followed by inquiry and observation is substituted for unquestioning credulity. We are informed, for example, that the poisons which cause convulsions are sometimes largely held in solution by the dropsical effusions, and that it is when these effusions are rapidly reabsorbed into the blood and conveyed through the cerebral circulation to the brain that the severer nervous symptoms of uræmia are manifested. Yet here was a lad who had convulsions every five minutes, where the œdema was so great as to make him scarcely recognisable by his nearest friends, and none at all while the process of reducing him to rational dimensions was in active progress; and I recall the case of a youth in this hospital where the œdema and the rapidity of absorption were greater than I have ever seen either before or since, where it was impossible to see the pupil of one eye because of the s[illegible] the amount of urine rose in [illegible]nces in the 24 hours, but w[illegible] convulsion. Equally conclus[illegible] assumption made by the same author that the urine in these circumstances *constantly* becomes alkaline within 24 hours. "I think it likely," such are the exact words used, "that the [illegible] urine in this and other cases [illegible] decomposition, and that it is [illegible] urine collected over 24 hours shows so constantly this alkalinity." But this lad's urine is *very* albuminous; it contains 2·3 per cent. of urea; it has been in my testing room, partly in a bottle and partly in a urine glass simply covered with paper, for 12 days and yet it is not in the least degree decomposed nor has it lost any of the acidity which it had when I took it from the patient's room. Indeed, so entirely free is it from any trace of decomposition that one might have thought some antiseptic had been added to it. If any antiseptic is present it must be one that was formed during the abnormal chemical processes which constituted the disease, and this may or may not have been the case. We have no evidence one way or the other, but I have as much reason for saying that in uræmic convulsions an antiseptic of a highly toxic and convulsivant nature is formed—a proposition which I should by no means like to advance—as the author in question has for speaking of the *constant* alkalinity of albuminous urine. Indeed, I think I may have more reason as I not infrequently find that the urine passed next after epileptic convulsions remains undecomposed for a long time. I have one sample in my testing room now which was passed in April, 1904, and is yet acid and entirely undecomposed.

Lastly, I will direct your attention to a case which I think you have all seen; and I do not so much because it illustrates any particular kind of treatment, though one phase of it has a practical bearing on treatment, as because it points to the necessity of acquainting yourselves thoroughly with facts and of not allowing yourselves to be argued out of them on any consideration whatever.

Case 5.—On Feb. 17th, 1905, a sailor, aged 43 years, was brought to the hospital from the Sailors' Home. Dr. Salisbury, the senior house surgeon, saw him at once and found pleuritic friction in the left axillary region, dulness of the right pulmonary base, general congestion of both lungs, a swollen and acutely painful right shoulder-joint, great distension of the abdomen, and a large slough on the anterior part of the tongue. When I saw him an hour or two later I verified all these facts. They were all, except the abdominal distension and the lingual ulcer, much intensified on the following day, when for the first time I learned that he had been admitted to the Sailors' Home on the 13th, had gone to bed in a state of intoxication, had turned on the gas without lighting it in a small room of between 500 and 600 cubic feet capacity, and had been found by the night watchman some considerable time later unconscious and all but asphyxiated; that he had been removed to the passage and artificial respiration practised for three hours, at the end of which time he was sufficiently restored to be replaced in his bed. On the 17th he was brought to hospital in the condition which I have mentioned. The extreme pain in the right shoulder and the slough at the tip of the tongue were presumably caused by drawing the tongue forwards with forceps and by the forcible movements of the arms in performing artificial respiration. The abdominal distension was at once relieved by the use of a turpentine and asafœtida enema consisting of half a drachm of asafœtida and one ounce of oil of turpentine in a pint of warm starch. The patient died at 11.30 P.M. on the 18th. At the post-mortem examination which was made as usual by the pathologist, Dr. J. L. Dimond, all the facts disclosed by examination during life were verified—viz., consolidation of the lower half of the right lung, extensive pleurisy with large flakes of adherent lymph on the left side, and general pulmonary congestion. This condition in a man who had gone to bed intoxicated six days before and who had added the poison of coal-gas for several hours to the poison of alcohol, and, lastly, had had the merciful but necessarily somewhat rough discipline of artificial respiration employed for three additional hours, was quite enough to account for his death. During the examination I was surprised to hear that the coroner, who had, of course, been communicated with, had expressed a desire that the honorary physician should attend to give evidence as well as the senior house surgeon, whose attendance in ordinary circumstances is alone required, and on the following morning I received a formal summons. Happily, a casual expression made use of by one of yourselves in the post-mortem room to the effect that the gas company were to be represented at the inquest and that there was a fear that the man might have died from carbon monoxide poisoning due to the inhalation of water gas supposed to be mixed largely with the coal-gas supplied to the district caused me to return to the body and carefully re-examine all the facts so as to ascertain any evidence bearing upon this point. I could find none and I am quite at a loss to conceive how the idea could have originated. There was no cherry-red colour of the mucous membranes of the lips, &c. The livid patches on the skin were just such as are found in other cases. The blood, if it differed in any respect from that of a patient dying in other circumstances, did so in being somewhat darker rather than brighter in hue. I show you here some that has been largely diluted side by side with some equally diluted but obtained from another body and I think you will all recognise that it is somewhat darker. Lastly, I had just time to submit it to spectroscopic examination and I found nothing whatever to countenance the idea that it contained a large proportion of that gas. I show you here a drawing of the spectrum of blood containing carbon monoxide. The absorption lines and bands between D and E and the absence of these far beyond F are pretty distinctive. I examined it carefully with the double prism Browning spectroscope with which I work and I saw no evidence whatever to support the hypothesis that the man had been poisoned by carbon monoxide. If he had been picked up in the open street with signs and symptoms such as he presented when admitted he would probably have died and his death then would have been attributed to natural causes. "But might not carbon monoxide have accelerated his death?" was one of the questions then put to me. The reply was that there was not the slightest appearance either during life or post mortem of his ever having breathed any considerable proportion, or indeed any at all, of that gas. I agreed, of course, that to put a drunken or even a sober man into a bedroom not much if any larger than an ordinary closet and then to turn the unlighted gas on for a long space of time was not a proceeding likely to improve his health; but all the questioning and cross-questioning to which I was submitted failed to elicit an opinion that the man had breathed anything more injurious than ordinary coal-gas. After having firmly maintained this opinion it was some satisfaction to me to hear from the next witness, a responsible representative of the Liverpool Gas Company, that no water-gas whatever was at that time being supplied to the district in which the sailors' home is situated; and I could not help wondering how I might have felt if after manifesting an extraordinary amount of acumen in pointing out the subtle distinctions by which this poor fellow could be proved on scientific evidence to have suffered from water-gas poisoning I had heard it established on oath and beyond the possibility of doubt that he could not have breathed any.

The Lumleian Lectures
ON
NUTRITION AND MALNUTRITION.

Delivered before the Royal College of Physicians of London on March 28th and 30th and April 4th, 1905,

By W. H. ALLCHIN, M.D. Lond., F.R.S. Edin.,
FELLOW AND CENSOR OF THE COLLEGE; SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

LECTURE II.[1]

Delivered on March 30th.

Mr. President and Gentlemen,—Passing now to consider a little more in detail the changes undergone during digestion and subsequent absorption of the different alimentary principles, it will be found that the general result of the hydrolysis is to convert the normal substances into bodies somewhat less complex in character but becoming at the same time more diffusible. Such changes therefore are destructive or analytic in nature. Inasmuch, however, as it is most certain that the materials as presented for assimilation by the bioplasm are not (with few exceptions, chiefly among the inorganic ingesta) in the form in which they occur in the food, nor even as they are after undergoing digestion in the alimentary canal, some further changes must be undergone by them, somewhere between the surface of the gastro-intestinal epithelium and the living cell into which they will be incorporated, and these changes for the most part are of a synthetic character. Whatever may be the nature of the agencies by which these latter changes are effected, it may be said that those which take place in the alimentary canal are fairly well understood and are capable of more or less exact imitation in our laboratories by well-recognised chemical methods, while those changes which commence with the gastro-intestinal epithelium, though possibly and even probably of the same nature, are not so readily imitated by the means at present at our disposal, and that with the absorption of the digested material the direct influence of living protoplasm is for the first time brought to bear on the aliment. At the same time it is admitted that the digestive processes themselves are effected by the products of bioplastic activity—viz., the ferments—and it may well be that after all the subsequent elaboration of the nutriment is effected by similar agencies.

The Digestion, Absorption, and Destination of Proteids.

First as regards proteid digestion. In whatever form these bodies are presented to the digestive organs, whether as albumins, globulins, fibrins, &c., they are converted into a diffusible condition by the pepsin of the gastric juice acting in association with hydrochloric acid and by the trypsin of the pancreatic secretion in the presence of an alkali. I am not now concerned with the different views taken as to the nature of the several stages of decomposition which these proteids undergo, it is sufficient for my present purpose to understand that it is mainly into albumoses and peptones that proteids are converted. Whilst we are ignorant of the exact composition of the different members of this group it is impossible to say precisely how the peptones differ in their chemical structure from the proteids whence they have been derived nor what different kinds of albumoses and peptones there may be. It is by their physical characters that they are distinguished, by their non-coagulability, by their differences in diffusibility—i.e., size of molecule—and in precipitation by ammonium sulphate, as also by their fractional heat coagulation.

Although it is the case that in the normal process of proteid digestion the hydrolysis by the gastric ferment does not proceed beyond the stages of proteoses and peptones and that a much further cleavage takes place by the action of trypsin, whereby a large proportion of the ingested proteids are ultimately decomposed into much simpler crystalline substances, represented by leucin and tyrosin, and other amido-acids, as well as lysine, lysatine, argenin, and a body called tryptophan, it is not to be supposed that the difference is other than one of degree, for under certain artificial conditions outside the body the pepsin action may be made to effect very nearly the same ultimate results as the pancreatic enzyme. It may be observed, however, that the extent to which the peptones and albumoses are further split by the trypsin is much greater when those bodies have been formed by gastric digestion than when the pancreatic ferment works straight away upon native proteids. This, so to say, natural trend of the proteolytic enzymes is an important fact. If also it is recollected that neither proteoses nor peptones are to be found in the portal vein and that if such bodies gain entrance to the circulation they are at once eliminated by the kidneys, and also that the amido-acids are not found in normal fæces or urine, the question of the form in which the proteids are absorbed into the circulation comes to assume one of considerable interest if not difficulty. At least it cannot be that the general character of the changes which intervene between the proteids as ingested and as they are ultimately presented to the bioplasm consists merely in a series of transformations among closely allied bodies, such, for instance, as is in great measure the case in connexion with the carbohydrate digestion and assimilation. The changes in the proteids clearly extend over a much wider range than that and further, having regard to the fact that the proteid constituents of the tissues are by no means identical with those taken as food, it is clear that synthetic processes of an extensive character are involved. At first sight it would appear that a decomposition of the nitrogenous aliment into bodies so much less complex as the amido-acids are, as a preliminary to their reconstruction into tissue constituents of even greater complexity, is a wasteful exhibition of energy, but a comparison of the calorie value of these amido-acids with that of the proteids from which they have been obtained shows that only a very slight loss of energy has been sustained. Some of the difficulty in connexion with this subject has been cleared up by the discovery by Otto Cohnheim of a ferment in the cells of the intestinal epithelium to which he has given the name of "erepsin," and by this agent the albumoses and peptones which are absorbed are split up into cleavage products such as amido-acids, in which form the bulk of the nitrogenous ingesta passes into the blood and so to the liver.[2]

That the end products of tryptic digestion can be made available in the economy has been shown by dogs in a state of nitrogenous equilibrium if fed on these bodies still maintaining that equilibrium, showing that proteids need not retain their characteristics to be available as food and that their cleavage products can supply the essentials for tissue nutrition. In those conditions where a transference of the proteid constituents of some tissues to others takes place it seems probable that their passage takes place in the form of cleavage products and not actually as proteids. Such, for instance, in starvation when a great loss of the systemic muscles occurs and also of glands rich in proteid matter, whilst but little loss takes place in vital organs like the heart, the muscular tissue of which is maintained at the expense of these other structures. To effect this transference of proteids from one tissue to another it is clear that they must be rendered soluble and diffusible; in other words, digested and the wide distribution throughout the tissues of proteolytic ferments and also, as Dr. Vernon has shown, of erepsin,[3] would seem to suggest that it is by their agency as in the intestine that the change is effected. Support for this view is also to be found in plants, since "in vegetable metabolism the amides have been shown to be antecedents of proteid or to take part in its construction disappearing from the cell as proteid is formed."[4]

There has always been a considerable difficulty in accepting the view that the absorbed peptones and albumoses were retransformed into coagulable proteids such as serum globulin and serum albumin in their passage through the villi to the blood current, for among other reasons it is known that in starvation the circulating proteids in the blood are but very slightly diminished in amount, in marked contrast to the decrease of the tissue proteids, and were the former the nitrogenous pabulum they would be expected to disappear Moreover, neither of these circulating proteids corresponds to the actual proteids of the tissues, in each of which a further special transformation would have to take place But with a preliminary decomposition of the proteids into bodies of an altogether simpler character there is presented to each living unit the raw material, so to say, out of which each can synthesise for itself its own special constituent and this without, as already said, any material loss of potential energy Further than this, there is some reason to believe that the proteid cleavage may proceed in the intestines beyond even the formation of the amido acids, even to the splitting off of the nitrogen and formation of ammonia, and this would account for the large excess of ammonia which is found in the portal blood It is not suggested that more than a small quantity of the proteid is split up to this extent and the non nitrogenous moiety of the molecule probably serves as fuel in the course of the subsequent metabolism

---

[1] Lecture I. was published in The Lancet of April 29th, 1905, p. 1111.

[2] Dr. Vernon, Journal of Physiology, December, 1903, has shown that the pancreatic secretion also contains erepsin, which is quite distinct from the trypsin, and that it differs somewhat from the intestinal erepsin.

[4] Ferments and Fermentation, by Professor Reynolds Green, F.R.S. 1901.

Although this account of the changes undergone by the proteids in the intestine represents the most recent views on the subject there have lately been made some observations which, so far as they go, are more in the direction of supporting the older views It has for long been known that a milk curdling ferment, rennin, is secreted by the stomach, and more recently it has been shown that a similar body is found in the pancreatic fluid Besides its specific action upon the caseinogen it also has an action on the albumoses and peptones which it meets with in the intestine, altering them in such a manner as to increase the size of their molecules and so forming a colloidal body to which the name "plastin" has been given, that is intermediate between the albumins and the albumoses and in an alkaline medium resembles a coagulable proteid and so differs from peptones That is to say, there is here a synthetic change tending to raise the less complex non coagulable albumoses to a higher stage of complexity towards that which obtains in the actual proteid construction of the tissues Considerable difficulties surround the subject, not the least being the mode in which the absorption of this substance takes place and the doubt already referred to concerning the circulating proteids being assimilated by the protoplasm May it be that the occurrence of rennin in the stomachs of birds and fishes where no milk curdling takes place is connected with this additional action?

If now we endeavour to follow so far as we can the destination of the digested proteids we are at once struck by the fact already mentioned that if they be presented for absorption as albumoses and peptones these bodies are not to be found in the blood of the portal system, far less in the general circulation Moreover, such bodies are extremely toxic in character and should they in any circumstances find their way into the blood current would be eliminated by the kidneys at once Somewhere, then, in the passage of the digested proteids through the columnar epithelial cells or in the lymph of the underlying lymphoid tissue, whence they are absorbed into the portal blood, they are reconverted into coagulable proteids possessing no characters at present distinguishable from those of the normal blood Everything points to this change, if it really occurs taking place in the epithelial cells If, on the other hand it is in such form as leucin and tyrosin that the digested proteids are absorbed their passage into the blood offers no difficulty, but at the same time no special excess in the quantity of these substances is found in the portal vein, which is explained by the advocates of this view as being due partly to the difficulties connected with the quantitative estimation of these bodies in such fluids as blood, and partly to the relatively small quantity existent at any one time and the rapid disposal of it by the liver

In passing, it may be remarked that a considerable difference exists in the extent to which the various proteids of the food are absorbed, dependent no doubt in great measure, if not wholly, on their digestibility (in the absence of any evidence to indicate a selective power of absorption by the epithelium) Thus, vegetable proteids—probably from their association with cellulose and other materials—are commonly less well absorbed than those of animal source, though by no means in all cases, and even among those of animal origin differences exist At the same time it may be remarked that native proteids are capable of some absorption without change, and a still larger amount of alkali and acid albumin may be taken up without previous conversion into albumoses or peptones

[illegible] the albumoses and peptones are reconverted by the intestinal epithelium into such proteids as are normally found in the blood, it is held that ' the great part of the proteid which is absorbed from the intestine passes on through the hepatic veins into the general circulation without being stored or at once modified in the liver "[5] If, however, it is in the simpler form of such bodies as the amido acids and their allies that the digested proteids reach the liver then it would seem probable that certain synthetic changes—comparable to those taking place in the kidney cells by which benzoic acid and glycocoll are synthesised into hippuric acid—are effected in a portion of them by the hepatic cells preparatory to their being assimilated by the protoplasmic molecule On experimental grounds it is probable that the greater part of the amido acids are converted into urea in the liver and if, as has been said, the bulk of the ingested proteids are split into these and allied substances during digestion and in the intestinal epithelium then it would appear that the ordinary nitrogenous intake far exceeds the requirements of the body and gives support to the view which Chittenden's experiments indicated Of the importance of the liver in the metabolism of proteids and strongly confirmatory of the view that it is as comparatively simple cleavage products that the digested proteids reach that organ is the fact that in acute and extensive destruction of the liver cells as occurs in phosphorus poisoning yellow fever and the like, leucin and tyrosin are found abundantly in the urine, being thus excreted, it may be reasonably supposed, since the liver had been unable to deal with them as it does in normal circumstances Thus the function of the liver in this case resembles that in respect to the absorbed [illegible], [illegible] ot the products of proteid and of [illegible] either store them up as glycog[illegible] genous bodies into less diffusible albumins and globulins and so retain them in the economy, and on failure of hepatic function they would pass on unaltered and be excreted by the kidneys as sugar and amido acids respectively

The solution of the problem which concerns the mode in which the proteids are actually disposed of by the living tissues will depend in some measure upon our knowledge of the precise form in which these substances are presented for assimilation Of the views most generally held hitherto one is that whilst a portion of the absorbed proteids are ultimately incorporated into the bioplasm—forming the so called ' tissue (Voit) or organised proteid—whereby its growth and maintenance are effected making up that is, for the wear and tear, a large proportion never becomes an integral part of the living molecule which by contact—or as we should now say by ferment action—induced in this so-called "circulating (Voit) or unorganised proteid katabolic changes akin to those determined in the fat and carbohydrate which are also associated in the protoplasm By Pflüger, however and with perhaps the more general support of physiologists the whole of the proteid intake was considered to become bioplasm leading to increased growth and metabolism of this material with production of body heat, of which the muscles are the chief source If however, the nitrogenous pabulum is presented to the bioplasm in a simpler condition than that represented by serum globulin and serum albumin, as we have seen reason to believe may be the case, in such a form as leucin tyrosin, or allied substances then a greater range of synthetic change is called for on the part of the living matter to render such bodies an integral part of itself

The subject of proteid katabolism is one of exceeding complexity Without doubt the most abundant nitrogenous waste substance is urea and the amount excreted varies directly with the quantity of proteid food Inasmuch, also as the muscles form the great bulk of the proteid tissues it is from their waste that the greater quantity of the urea is derived At the same time, however, it is pretty certain that the urea is not formed in the muscles but in the liver, which thus becomes an organ concerned in the katabolic processes of nutrition as it is with the anabolic processes that I have before said are to be regarded as in great measure coincident and mutually related From this it would follow that some or all of the products of the disintegration of muscular tissue in the exercise of its function must be conveyed to the liver, there to be converted into the urea which is excreted. These substances are included under the general term of extractives and consist of creatine and creatinine, uric acid, xanthin and hypoxanthin, &c. None of these bodies, however, is the immediate precursor of urea, the actual substance being a compound of sarcolactic acid, a constant result of muscular action, and of ammonia which is another product of the same. The ability of the liver to form urea from certain ammonia salts has long been known and there is very little doubt but that it is in this manner the muscle waste is disposed of so far as the nitrogenous part is concerned, the non-nitrogenous portion forming, as will be immediately seen, a carbohydrate, being finally eliminated as carbonic acid and water. That a large proportion of the urea excreted is formed by the liver from the leucin and tyrosin which have resulted from proteid digestion has already been mentioned.[6] Another important product of proteid decomposition is uric acid, concerning the origin of which under normal and abnormal conditions most diverse opinions have been held. Here it will suffice to say that its origin, as that of other purin bodies, is to be found in the metabolism of the nucleo-proteids, and hence it is a product of nucleated cell activity such as occurs in secreting glands and the white cells of the blood.

---

THE DIGESTION, ABSORPTION, AND DESTINATION OF CARBOHYDRATES.

Having thus traced the proteid elements of the food from their ingestion to their presentation to the living cell it now becomes necessary to pursue the same inquiry in respect to the carbohydrate food-stuffs. Here the subject is somewhat easier though much still remains to be learned. In whatever form these constituents of the food are offered, whether as starch, dextrin, gums, or as cane sugar, milk sugar, or maltose, they are only assimilable in the form of glucose (dextrose, levulose, &c.) and for the most part are absorbed into the blood in this form. Should such substances as cane sugar or maltose gain entrance as such into the blood they are excreted by the kidneys and are not made use of. Inasmuch as the greater part of our ingested carbohydrates is in the form of starch or cane sugar it is clear that during their course through the alimentary canal they must undergo certain changes which result in their conversion into the glucose form. The nature and agency of these changes are fairly well understood and are briefly a succession of hydrolytic actions effected in the case of polysaccharides $(C_6H_{10}O_5)_n$ such as starch by the diastatic or ferment action of (*a*) the salivary ptyalin, which is carried on almost entirely in the cardiac portion of the stomach unless the act of chewing be excessively prolonged; and (*b*) of the pancreatic amylopsin, by which the bulk of the material is converted into the disaccharide $(C_{12}H_{22}O_{11})$ maltose, and subsequently the conversion of the maltose into the monosaccharide $(C_6H_{12}O_6)$ dextrose by the inverting ferment of the succus entericus and, as appears to be very probable, by the action of the intestinal epithelial cells during the passage through them of the absorbed material The ingested disaccharides will, of course, only undergo the inverting action, a small amount of which may be effected by the acid of the gastric juice (comparable to the action of dilute mineral acids on cane sugar or maltose in the laboratory), as was shown by Ferris and Lusk,[7] the latter of whom has lately proved the absence of a cane-sugar inverting enzyme from the gastric juice.[8]

As with the digested proteids so the digested carbohydrates are absorbed by the epithelial cells of the small intestines and to a much lesser degree by those of the stomach, the rate of absorption being influenced by various circumstances, such as the degree of concentration, the rate of the blood current, and so on. I have just mentioned that these cells most probably exert an effect on the maltose, changing it into dextrose; as there is reason to believe they modify the other products of digestion as they pass through them. By the portal vein the dextrose is conveyed to the liver where it is partly reconverted by a process of condensation into a polysaccharide, glycogen, and stored as such in the hepatic cells; some passes through the liver and is laid up in the tissues, more especially the muscles, also as glycogen, though a considerable proportion, as will be seen, is converted into fat. It is further supposed that in addition to these destinations of the dextrose some enters into the construction of certain of the proteids and nucleo-proteids, forming within the molecule an atom group of the nature of a hexoglucose, the basis of what I referred to in my previous lecture as the glucoside theory of proteid constitution. Dr. Pavy has strongly adopted this view and has shown that from many proteids—though not from all—a body of glucose character can be obtained on treatment with caustic potash as it was previously known could be effected by dilute acids. That such a notion as to the destination of part of the carbohydrate intake is highly probable might be inferred from the fact that within the body the proteids—or at least some—are the source of some of the carbohydrate nutriment. It is well known that glycogen continues to be formed in animals who are fed on a diet absolutely free from carbohydrates and it is almost certain that the fat is not the origin of this substance; there remains only then the proteid aliment as a source. Some of this proteid-derived carbohydrate, like that ingested, may be stored up as glycogen and some may be circulated as dextrose and consumed without condensation into glycogen. That plants such as yeast cells may synthesise proteid matter from sugar, ammonium nitrate, the ash of yeast, and water is established, thus showing that carbohydrate matter is incorporated into the proteid in the course of its construction, and correspondingly from the proteid the carbohydrate may be split off in certain circumstances to be used up in the tissues.

There is, then, but little evidence of synthesis of carbohydrates within the animal body, whether from the food constituents or from any products of decomposition of tissue elements; such anabolic changes as do occur in these substances are of the nature of transformation among isomeric substances or of condensation of various saccharides effected by various enzymes each adapted to the special change required. This is in marked contrast to what obtains in plants, where a most extensive formation of starch, sugars, cellulose, and allied substances is effected by the synthesis of much simpler bodies of which carbonic oxide and water are the chief, or sometimes even of the elements themselves.

It is as glucose that that portion of the carbohydrate ingesta not converted into fat is ultimately used by the bioplasm, the stored glycogen being reconverted for that purpose, and the decomposition of the sugar in the muscle is effected by a ferment, which may be extracted in the muscle juice, acting in conjunction, as Otto Cohnheim has shown, with a probable ferment body formed by the pancreas and thrown into the general circulation in a manner comparable to the combination of enterokinase and trypsinogen already described. The final products of the destruction of the carbohydrates are carbonic acid and water which are excreted by the ordinary channels but there is reason to believe that among the intervening products of oxidation are lactic acid, alcohol, and aldehyde.

THE DIGESTION, ABSORPTION, AND DESTINATION OF FATS.

The fats of our food, derived as they are from both animal and vegetable sources, differ somewhat, but not entirely, from the chief fats found in the body—viz., tripalmitin, tristearin, and triolein. However fine the emulsion may be in which they are presented to the intestinal mucosa for absorption the molecules are still too large to pass into the epithelial cells on their way to the lacteals. It is almost certain that it is not in this form that the fats are absorbed for, among other reasons, although fat granules and globules are abundantly to be seen in the interior of the intestinal epithelial cells during digestion, they are never to be found in the striated border of those cells. Everything points to their being saponified, that is, split up into glycerine and fatty acids, the latter uniting with alkalies in the intestine to form soaps. These, which are moderately soluble, are absorbed together with the glycerine, to be reconverted into neutral fats within the epithelial cells, whence the particles and globules are conveyed by leucocytes into the lacteal radicles in the villi, finally to reach the thoracic duct. In the most favourable circumstances it is only a part of the absorbed fat which ultimately reaches the circulation; a considerable amount is in some unknown way disposed of *en route*, possibly in the lymphatic glands.[9] The effective agents in bringing about the saponification of the fats in the bowel are the alkaline bile and pancreatic juice, the latter of which contains a special fat-splitting ferment—steapsin. Although the exclusion from the intestine, either artificially or by disease, of these two secretions is followed by the presence of fatty matter in the stools it is chiefly in the form of fatty acids that fats are there met with, showing at least that the presence of these juices is not wholly essential to the fat-splitting, however important may be their influence in saponification and still more in facilitating the absorption of these materials. It seems that some fat-splitting occurs in the stomach, though much less than what takes place in the intestine, but very little formation of soap, however, takes place in that organ.

---

[6] A ferment—argenase—has been found in the liver and other organs by which argenin, one of the products of proteid cleavage, is converted into urea.

[7] American Journal of Physiology, 1898.

[8] Ibid., February, 1904.

[9] Schafer: Text-book of Physiology, vol. i., p. 462.

Inasmuch as a great part, often the greater part, of the fats of the food differs somewhat in composition from the fats found in the body it would follow that if the former be the immediate source of the latter they must undergo some change. Moreover, it is by no means certain that such ingested fat as does correspond to that of the body directly goes to form the fat as it occurs in the tissues. That it may do so, however, appears possible from the fact that fats which do not normally occur in the tissues may yet be found there when administered with the food. Ordinarily fats form but a small proportion of the total ingesta but they constitute a very considerable part of the body weight and are the chief reserve store of potential energy. It is clear, therefore, that there must be some other source or sources of this material than that contained in the food and this is to be found chiefly in the carbohydrates from which it is well known the body fats are largely derived. Fat synthesis, therefore, becomes an important factor in nutrition. That there is a synthesis is obvious from what has just been said of the digestion of fats; the fatty acids and glycerine into which these substances are split up in the intestine for purposes of transference are re-combined in the epithelial cells to form the fat which is in great part stored. It has also been found that dogs fed upon fatty acids only were nevertheless able to lay up neutral fats, the synthesis in this case not only combining the acid and glycerine but also forming in some way not known the glycerine itself. It has been recently held that the fat-splitting enzyme or lipase which acts upon the fats in the intestine is the same agent that effects the condensation of the results of the cleavage—viz., the glycerine and fatty acid, an instance of what is termed "reversible action."[10]

As to the manner in which carbohydrates are converted into fats precise information is wanting, but it appears probable that it is the products of disintegration of the former that are synthesised. Among those products it will be remembered that lactic acid is prominent and that the same substance is formed from sugar of milk by an organism and is the well-known cause of milk "turning sour." Similarly butyric and caproic acid, lower terms of the fatty acid series, are formed from carbohydrates by another organism, lactic acid being first produced from glucose into which the carbohydrate is previously converted. The work of Leathes and others has shown it to be most probable that it is in the liver that the lactic acid is changed into butyric acid, as also that it is in the same organ that the butyric acid is built up into a higher term of the same series and that from the carbohydrates of the food first converted into glucose, and possibly from the glycogen of the tissues also converted into glucose, the several fatty acids—palmitic, stearic, and oleic—are in great part derived. Similarly, in the seeds of some plants oils are formed at the expense of the starch. Most probably also the glycerine with which the acid forms the neutral fat is derived from the sugars. In alcoholic fermentation of sugar by yeast this substance is known to be formed, which suggests an origin of a similar nature in the body.

It would be impossible in connexion with the origin of fat from carbohydrates to avoid reference to the views so ably advocated as the outcome of an almost life-long experimental study of the subject by our distinguished Fellow, Dr. Pavy. According to him a large proportion of the glucose resulting from the digestive changes in the carbohydrate food is stopped from entering the portal blood-stream by the intestinal epithelium, in the cells of which it is converted into fat, and in that form enters the lacteals. Such as escapes is condensed into glycogen in the liver, which in its turn is normally transformed into fat and not into sugar. Dr. Pavy considers that it is by the protoplasm of the cells that this conversion is effected and inclines to the view that the glucose becomes a constituent of the protoplasmic molecule previously to its giving rise to fat. I am not concerned to criticise this view; it is sufficient for my purpose to refer to it as indicating the very extensive transmutation of carbohydrate into fat that is held by some as normally taking place.

As to whether fats may be formed from proteids of the food or of the tissues the most opposite views have been held. At the one extreme was Voit who maintained that they were almost if not entirely so produced, and that even the carbohydrates did not give rise to them. The proteids, it was said, were so split up as to form a nitrogenous moiety which was thrown off as urea, the remaining portion consisting of carbon, hydrogen and oxygen only being stored as fat. That this was going too far was proved by the classical experiments of Lawes and Gilbert, by which the carbohydrates as being the chief source of the body fat was proved. It was still a question, however, whether any fat was formed from proteids and up to the present day it has generally been conceded that there is. The teaching of Virchow in respect to the fatty degeneration of proteid tissues has gone far to maintain this view. Quite lately, however, this explanation has been called in question, chiefly from the experiments of Rosenfeld, and there seems to be good reason to believe that in all cases of so-called "fatty degeneration" the fat is really transferred as such from some fat depot—adipose tissue or other—though admitting the possibility of a small amount being formed from the fat which is combined with the protoplasmic molecule or from such bodies as protagon and lecithin which are intimately associated with the proteid, but that in no case is fat a product of proteid degeneration.[11]

The katabolic changes which the fat undergoes are those of oxidation into carbonic acid and water without so far as is known the formation of any intermediate bodies, the combustion being complete. Most of the disintegration takes place in the muscles with the liberation of heat and chemical energy with transformation of the latter into muscular work.

A survey of the foregoing account,[12] necessarily brief, of the changes undergone by the ingesta subsequently to their digestion in the alimentary canal suggests several points for consideration, first among which are the conditions attendant upon their absorption by the intestinal epithelium. These cells, to which formerly was attributed the sole function of permitting the passage of the diffusible gastro-intestinal contents, are now seen to be possessed of powers of high metabolic value apart even from those scarcely less important which are concerned with the production of such a stimulus to pancreatic secretion as secretin or the actual formation of a special fluid, the succus entericus, with its specific powers. Upon two groups at least of the digested food-stuffs do these tissue elements effect an important change: the proteids are broken up into much simpler substances—amido-acids and allied bodies—and the fats which to permit of absorption had been split into their constituent acids and glycerine are re-formed by them. Upon the glucose into which the ingested carbohydrates have been converted less unanimity of opinion prevails; whilst some consider the sugar passes through unchanged into the portal blood, others with Dr. Pavy consider that this is prevented by the change into fat undergone by the glucose in these same epithelial cells.

---

[10] Hanriot: Comptes Rendus, vol. cxxxii., 1901.

[11] An interesting summary of the evidence bearing on this point is given in a paper by Dr. Christian of Boston in the Johns Hopkins Hospital Bulletin for January, 1905. On the other hand, it is generally admitted that fat is formed by certain micro-organisms, especially the bacillus tuberculosis, to the large quantity of fat [illegible] in great [illegible] h. 1904). [illegible] with the [illegible] amounts [illegible] ot be the [illegible] only have [illegible] e formed [illegible] oteids and [illegible] ast, from some cleavage product or products other than the carbohydrate portion (Beebe and Buxton: American Journal of Physiology, vol. xii., No. 5, 1905).

[12] I have not thought it necessary in this account to take into consideration the action of micro-organisms in the alimentary canal upon the ingesta. That they are not absolutely necessary to the maintenance of normal nutrition has been demonstrated and that they may be [illegible]

Another feature which stands out from our more precise knowledge of these processes is the relation of the liver to the several groups of materials brought to it in the portal vein. In respect to few organs of the body have opinions so much varied from time to time as they have in regard to the functions of the liver, and although we cannot yet speak precisely as to what changes may be effected by the hepatic cells in the proteid products of digestion, if, indeed, any change be effected, we clearly recognise that glucose is stored partly as glycogen and partly as fat, the synthesis of the fatty acids having been shown to take place in this organ. From the katabolic side the liver also occupies an important position, since it is in that organ that the chief nitrogenous excreta are synthesised into that form in which they are finally eliminated.

The more accurate realisation of the metabolism of the food-stuffs leads to a wider conception as to the nature of the pabulum as offered to the living matter and the relative importance of the several constituents. Such proteid synthesis as takes place is concerned with some of the products of proteid destruction in the course of their elimination. But certain portions of proteid cleavage become utilised as fresh food, whether it be in carbohydrate form or as fat. From the former of these the chief bulk of the latter is constructed but there is no conclusive evidence to show that the reverse takes place and that sugar may be derived from fats. Thus the residues of katabolism, whilst in part eliminated as waste, partly go to form those materials which play an important part in the economy, whether as internal or as external secretions, and are to some extent synthesised into the integral constituents of living matter.

Even yet more important is the recognition of the fact that the pabulum, whether proteid, fat, or carbohydrate, is ever in a state, as it were, of flux, now stored up, now transferred elsewhere, again perhaps to be stored up before it undergoes its final changes and is eliminated. To enable the laid-up materials to undergo this translocation they must be rendered soluble for conveyance in the blood or lymph streams and this is done by the agency of ferments of the same nature as those the ingesta met with in their process of digestion in the alimentary canal. The occurrence within the living cells both animal and vegetable, of ferments which are capable of digesting the cells is almost if not quite universal. Such autolytic enzymes are proteolytic in action and hence must be largely concerned in the ultimate proteid metabolism. If they be regarded as possessed of reversible power it would follow that by their means is maintained "a nitrogenous equilibrium within the cells, building up and breaking down proteids as circumstances require."[13] Reference has already been made to the widespread occurrence throughout the tissues of erepsin. So also a glycolytic enzyme is to be found in muscles and elsewhere; and lipase with its reversible power has been met with in a number of tissues, especially when fat synthesis occurs, such as the mammary gland when active and adipose tissue, also, too, in the liver and blood.

(To be continued.)

TEN ABDOMINAL SECTIONS FOR ABNORMAL PREGNANCIES AND OBSTRUCTED LABOURS.[1]

BY J. SCOTT RIDDELL, M.A., M.B., C.M. ABERD.,
SENIOR SURGEON AND LECTURER ON CLINICAL SURGERY, ABERDEEN ROYAL INFIRMARY; EXAMINER IN CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

HAD a surgeon 20 or 30 years ago ventured to read a paper to this society on questions affecting pregnancy and labour he might have been arraigned for trespassing on the preserves of the obstetrician and general practitioner; if in his paper he had discussed a series of abdominal operations performed during pregnancy a further charge of malpraxis would surely have been preferred against him. But the [illegible] uterus is no longer a *noli me tangere* to the surgeon, for [illegible] it and its adnexa are now attacked for myoma or inflammatory tumour with little risk to mother or fœtus. The surgeon, moreover, can now legitimately claim to have a professional interest in complicated pregnancy and labour, for it is through his work that obstructed labour and ectopic pregnancy have lost many of their terrors. True it is that these complications are uncommon. Infrequency is the cause of their being forgotten and their study neglected. It is also my apology, if such be required, for bringing before you ten cases of abdominal section for obstructed labours and abnormal pregnancies which have occurred in my practice. A discussion on this subject should be valuable, not only from its scientific interest but also from its practical application, in so far as it may lead to a determination of what is possible and proper in the treatment of these emergencies, which require immediate recognition and skilled interference.

For the sake of clearness and to facilitate discussion I have divided the cases as follows: (1) two cases of ovarian tumour obstructing labour; (2) two cases of uterine fibroid, the one obstructing labour, the other complicating pregnancy; (3) four cases of extra-uterine pregnancy; (4) a case of tumour narrowing the pelvic outlet and necessitating Cæsarean section; and (5) a case of omental adhesions disturbing pregnancy.

1. *Ovarian tumours obstructing labour.*—A discussion on the removal of ovarian tumours during pregnancy was held by this society in 1897 on a case reported by me. Since that time this question has been much under review and it is to a member of this society that the profession is indebted for the most valuable and complete work on the subject. Dr. R. G. McKerron, in his book on "Pregnancy, Labour, and Child-bed with Ovarian Tumour," has, after a laborious collection and masterly analysis of 1290 recorded cases, deduced certain rules for our guidance which have met with general approval and acceptance. For a full description of ovarian tumour, so far as it complicates pregnancy and the puerperium, I must refer you to Dr. McKerron's excellent monograph. The treatment, however, of ovarian tumour obstructing labour may fitly engage our attention for a short time to-night. It is summarised in the following conclusions, which I quote: 1. Ovariotomy is the best treatment and should be preferred when the patient can without delay be placed under the charge of an experienced operator. The abdominal is in general to be preferred to the vaginal route. 2. When time or place does not admit of ovariotomy reposition should be attempted but the effort to push up the tumour should neither be too forcible nor too prolonged. 3. In the majority of cases it will be possible to deal successfully with the complication by one or other of these methods. When both are found impracticable no time must be lost in carrying out the measures which circumstances dictate. The greatest danger is in delay. 4. The tumour should be either aspirated or preferably incised; when incised it should be stitched to the vaginal wall if time permit or, which is better, it may be evacuated and plugged with iodoform gauze. Both these measures are temporary and should be followed by ovariotomy as soon as possible after labour. 5. When the tumour is solid or semi-solid and only partially reducible by incision an attempt must be made, no matter what the circumstances, to remove it by the vagina or by the abdomen and if this fail Cæsarean section must be performed. In the hands of even an inexperienced operator this will involve less danger than an attempt to drag the child past the obstruction with the forceps. 6. Version is in all circumstances contra-indicated. Forceps or craniotomy must never be employed unless the obstruction has been completely removed. 7. In the abdominal operation for the removal of the tumour Cæsarean section should rarely be necessary. In almost all cases it will be possible to deal with the tumour by first drawing the uterine fundus through the abdominal wound or by getting an assistant to push the tumour up from the vagina, while the uterus is simultaneously pushed by the operator to one or other side of the pelvic brim. 8. Tumours which have been reposed or incised during labour must be removed as soon as possible in the puerperium.

The frequency of ovarian tumour complicating pregnancy is about 1 in 2500 cases. The maternal mortality in obstructed cases is about 25 per cent. over all the series; that of the children nearly 50 per cent. One-fourth of obstructing ovarian tumours are dermoids.

CASE 1. *Dermoid cyst obstructing labour, removed during subsequent pregnancy; recovery.*—The patient, married, aged

---

[13] H. G. Wells [illegible] o Proteid Metabolism. American [illegible]

[1] [illegible] Society of Aberdeen [illegible]

30 years, was attended at her fifth confinement in August, 1895, by Dr Kckerron For some time before labour set in she had been troubled with down bearing pain and irritability of the bladder Dr McKerron discovered when the os was half dilated that "the posterior vaginal wall was occupied by a flattened fleshy mass of about the size and thickness of a well developed placenta" He found it impossible to remove the obstruction, but with the assistance of Professor W Stephenson succeeded, under deep anæsthesia, in raising the tumour above the brim, when a living male child, considerably over the average size, was delivered with the forceps I saw the patient six weeks after her confinement and operation was advised She, however, did not arrange to come to the infirmary till ten months later when it was found that she was three and a half months pregnant A dermoid cyst of the right ovary, weighing 1 pound 12 ounces and with a very long pedicle, was removed in August and the patient made a good recovery, being delivered of a living female child the following January

CASE 2 *Dermoid cyst obstructing labour, reposition operation during puerperium, recovery* —(For the notes of this case I am indebted to Dr Thomas Fraser) The patient, aged 27 years, who was eight months pregnant, complained one afternoon in September, 1903, of a very severe vertex headache which lasted a short time and disappeared after a brisk walk The next afternoon she was seized with severe headache and suddenly went blind She was seen by a locum tenent who found her able to perceive light but she could only recognise that he was a stranger from his voice The urine was examined and found on boiling to be almost solid with albumin In the evening she had two severe convulsions for which one drachm of chloral hydrate was administered per rectum She had no more convulsions Labour started on the next morning and went on slowly A tumour was found on the left side a little in front of the head It could at first be pushed up but as labour progressed this could not be done Professor Stephenson saw the patient in the evening and under chloroform reposition of the tumour and delivery by forceps were easy The albumin in the urine diminished but there was slight elevation of temperature for a day or two She went to the Royal Infirmary on the fifth day after delivery and on the eighth day had a left dermoid cyst removed by me The tumour was lying in the pelvis and was flattened from pressure Albumin was present in the urine for a day or two before operation but it disappeared thereafter and the patient made an uneventful recovery In the beginning of December, 1904, she aborted at five and a half months, and at that time a tumour was felt on the right side of the abdomen She was examined under an anæsthetic by Dr Fraser and the tumour was diagnosed as a dermoid cyst of the right ovary which was found to be healthy at the first operation This tumour was removed by me on Saturday last You will see it is a dermoid cyst of about the size of an orange and containing much hair and one if not more teeth

2 *Uterine fibroids complicating pregnancy* —Bland Sutton has, under the title "The Inimicality of Pregnancy and Uterine Fibroids,' described the harmfulness of the association of these two conditions as being of three kinds (1) obstructive, (2) septic infection, and (3) degeneration of the fibroid The most extreme examples of the red degeneration described by Fairbairn occur in pregnancy, An examination of the literature on the subject shows considerable difference of opinion as to the tendency to abortion, the interference with labour, and the necessity for operative intervention in pregnancy with fibroid tumour Kelly s statistics seem to show frequent abortions as the result of the combination, while many observers, mostly continental, have found the reverse to be the case and maintain that operation is seldom required

Dr A Donald of Manchester, in an excellent paper on this subject published in the Transactions of the Obstetrical Society of London, vol xliii, 1901 gives his conclusions as follows 1 In the great majority of instances in which fibromyomata of the uterus and pregnancy coexist the course of the pregnancy and of the subsequent labour is not seriously influenced by the tumour but in a small proportion of cases the patient s life and the life of the child are seriously endangered 2 When pregnancy is found to be complicated by fibroid tumour it is best to allow the pregnancy to go to term as long as the mother's health is not seriously endangered 3 If at the outset of labour or shortly before it seems certain that the tumour will cause obstruction to the birth of the child Cæsarean section followed by hysterectomy should be performed 4 In cases in which the health of the mother makes it necessary to interfere in the earlier months abdominal section should be performed and an attempt made to enucleate the tumour 5 If in these circumstances myomectomy is found to be too dangerous hysterectomy should be performed

CASE 3 *Uterine fibroid obstructing labour reposed after cœliotomy, recovery* —The patient, aged 44 years, was admitted to the infirmary in June, 1902 at the request of Dr Gibb and Professor Stephenson She was in labour and the labour was obstructed by a tumour which they diagnosed as a myoma The tumour could not be reposed and it was thought that Cæsarean section would be necessary On opening the abdomen a myoma of about the size of a cocoanut was found impacted in the pelvis I found it quite impossible to get the tumour up past the pelvic brim and it was only after enlarging the incision up to the xiphoid and lifting the uterus out of the abdomen that sufficient space was given for the raising of the obstructing fibroid out of the pelvis While the uterus was swathed in warm sterile towels Professor Stephenson put on the forceps and speedily effected delivery After the placenta had been expressed the large abdominal wound was sutured The recovery was uneventful The age of the patient and her history decided me in not removing the fibroid, an operation which would only have added to the risks of the puerperium

CASE 4 *Pregnancy with large fibroid and adhesions, Porro Cæsarean section, recovery* —The patient, aged 42 years, was sent to me in August, 1903 by Dr S O Ironside of Fochabers She had a large abdominal tumour and Dr Ironside suspected either an ectopic or a complicated pregnancy On examination I found that she was pregnant about seven months and that the state of affairs was normal except for a large tumour lying in the abdomen to the left of, and attached to the enlarged uterus This was diagnosed as either an adherent dermoid cyst or a myoma and as it was painful and a likely source of danger it was decided to operate This I did on August 29th, when I found the tumour to be a fibroid From its relation to the

(a view with which

the tumour and gr

was done and she w

serrenoeud was used an instrument which I have found very useful in those hysterectomies in which rapid operating is advisable

3 *Extra-uterine pregnancies* —The recognition of this condition in its early stages is not easy In the later months though the diagnosis does not present much difficulty the exact line of treatment has to be determined according to the peculiarities of the case There is not absolute agreement among gynæcologists as to the ' how " and "when of the operation Werth has stated that during the early months extra uterine pregnancy must be treated as if it were a malignant growth In ruptured tubal gestation with active bleeding the indications for operation are as clear as in the case of a severed artery In pelvic hæmatocele (intraperitoneal) or the subperitoneal hæmatoma between the layers of the broad ligament some advise operation as the routine but the consensus of opinion is in favour of expectant treatment unless the absorption is slow or a tubal mole or abortion coexists This waiting involves a considerable period of invalidism and certain risks Among these a common sequela is suppuration and this is best met by vaginal incision and drainage

Ectopic gestation after the fourth month demands special consideration, as authorities differ on certain important points Bland Sutton says "The great risk of violent hæmorrhage from the placental site renders operation for tubal pregnancy between the fifth and ninth months of gestation, the fœtus being alive, the most dangerous in the whole range of surgery, hence it cannot be urged with too much force that when it is fairly evident that a woman has a tubal or broad ligament pregnancy *it should be dealt with by operation without delay* ' Kelly s dicta are "When a diagnosis of an unruptured extra uterine sac is made the operation should be performed with as little delay as possible " And again "If the child is viable the operation should be performed without waiting for the pregnancy to complete its term, as false labour may set in at any time and the child be lost " "If the child be dead it is better in such cases to wait several weeks to give the thrombi a chance to of which there are 7500 to the cubic millimetre, consist of the following varieties: 1. Polynuclear cells. These are large cells, from 9 to 10 μ in diameter, the protoplasm of which contains fine granules, which stain faintly with both acid and basic dyes. The nucleus of the cell is very inconstant in shape, sometimes appearing in the form of a horseshoe, at other times as if divided into several distinct parts. These cells form from 60 to 70 per cent. of the leucocytes. 2. Small lymphocytes, cells of the size of, or a little larger than, the red corpuscles. Their nuclei are round, indented, or even horseshoe-shaped, stain deeply with basic dyes, and are surrounded by a small amount of clear protoplasm. They form from 20 to 30 per cent. of the leucocytes. 3. Large lymphocytes. These are as large as, or even larger than, the polynuclear cells, the protoplasm is "hyaline," and the nucleus, which is rounded or oval, stains faintly with the basic dyes. 4. Transitional forms. These are similar to the last with the exception that their nuclei are indented or horseshoe-shaped. The large lymphocytes and transitional cells form from 4 to 8 per cent. of the white cells. 5. Eosinophile cells. These are similar to the polynuclear in size and shape but the protoplasmic granules are larger and stain deeply with acid dyes; they form from ½ to 4 per cent. of the leucocytes. 6. Basophile cells. These are rarely seen in normal blood and although similar in form and size to the polynuclear cells their cell granules stain only with basic dyes.

The blood of a child differs from that of an adult in the following particulars: 1. Shortly after birth it contains a greater number of red corpuscles; thus Sorensen[3] states that in male infants from five to eight days old the number is 5,769,500 and in the female child from one to 14 days old 5,560,800 per cubic millimetre of blood. According also to Cabot the number in the newly born is very high. 2. The white corpuscles are very numerous; this excess is most marked immediately after birth and then gradually falls; thus Da Costa says that at birth the count varies between 15,000 and 20,000 or even higher; this decreases after the first 48 hours and at the end of the first week has fallen to 10,000 or 15,000, which number is normal for children under one year of age. From the sixth year and upwards the number of leucocytes is 7500.[4] Of the different varieties of leucocytes in childhood the small lymphocytes are relatively more numerous—from 40 to 60 per cent.—and the polynuclears are less numerous—from 16 to 40 per cent.

In considering the effect which a given disease may have in altering the composition of the blood one ought if possible to eliminate all those factors, which, whilst not forming an integral part of the disease in question, yet may profoundly affect the blood. Of these influences the following are those which most concern us here: 1. Digestion. The effect of digestion on the composition of the blood has been very fully studied by numerous observers, all of whom agree that the number of leucocytes in the circulatory blood increases soon after the taking of food, rises to a maximum four or five hours later, and then gradually subsides; this increase averages 33 per cent. of the whole number of leucocytes.[5] In children this digestion leucocytosis is especially marked and in infants under two years of age it frequently rises to as high a figure as 30,000. What influence digestion has on the differential count is doubtful, some observers having found an increase in the polynuclear cells[6] whilst others have found a lymphocytosis.[7] After a meal, especially when considerable quantities of liquid have been taken, the red cells fall in number owing to a temporary dilution of the blood. 2. Loss of fluids from the tissues of the body, such as occurs in severe vomiting or diarrhœa. The blood being by these means temporarily concentrated, there will be an apparent increase of both red and white corpuscles in number.

With this brief description of the blood in health and its chief physiological variations I shall now pass on to consider in detail the cases of which this thesis is composed.

Section B.

In the examination of the blood of my cases I adopted the following methods. The percentage of hæmoglobin was estimated by means of Gowers's hæmoglobinometer and von Fleischl's hæmometer. For the enumeration of the red corpuscles the Thoma-Zeiss apparatus was used, the diluting agent being Toison's fluid. For counting the leucocytes the same pipette as that used for the red cells was made use of and, except where otherwise stated, at least 500 white cells were counted in making the differential count. The stains used for the blood films were Jenner's, Leishman's, and Ehrlich's triacid stains. Of the ten cases of meningitis which I examined eight were tuberculous in nature—namely, Nos. 3, 4, 5, 6, 7, 8, 9, and 10 (*vide* Table). No. 2 was also probably of the same nature, as although an examination of the brain could not be made, yet there was miliary tubercle of the intestines and peritoneum and the symptoms during life were fully in accordance with what one would expect in tuberculous meningitis; I have therefore considered it as belonging to this group. The remaining case, No. 1, was one of serous meningitis or hydrocephalus. Since the hæmoglobin findings exhibit no constant or characteristic features they may be dismissed as being of little value as an aid to diagnosis. The count of red cells was in most of the cases relatively high. Very little has been written on the behaviour of the red cells in cases of tuberculous meningitis and the only statement which I can find is that "the red cells show, as a rule, but slight changes, as is so often found in other forms of tuberculosis."[8] In six of the nine cases of tuberculous meningitis—namely, Nos. 3, 5, 7, 8, 9, and 10—there was no leucocytosis; of the remaining three, in two, Nos. 4 and 6, there was decided leucocytosis—namely, 42,000 and 21,000 respectively—and in No. 2 the count varied, on one occasion being 12,092 and a week later 27,000. From these results it is seen that in over 60 per cent. of cases of tuberculous meningitis there is no increase in the number of white cells. These results differ somewhat from those obtained by other observers; thus Cabot has recorded 27 cases, in 18 of which a leucocytosis was present; his results, however, are indecisive, since apparently the diagnosis was confirmed by necropsy in three only of the cases. In one case reported by Kneas a leucocytosis was present.[9] Rieder[10] has reported two cases, one showing a leucocytosis, the other a normal or subnormal count of white cells. Türck studied three cases, all showing a leucocytosis. Osler[11] says "a leucocytosis is not infrequently present throughout the disease." On the other hand, von Limbeck, in four counts made shortly before death, found no leucocytosis.[12]

As regards the percentages of the different varieties of leucocytes two points are to be especially noted—namely, a diminution of the number of eosinophiles and an increase in the large lymphocytes and transitional cells: thus in eight of the nine cases of tuberculous meningitis, Nos. 3, 4, 5, 6, 7, 8, 9, and 10, the relative proportion of eosinophile cells was below normal, in no case reaching ½ per cent. and in four cases they were entirely absent—namely, Nos. 4, 7, 8, and 10. These results are in marked contrast to the condition found in the case of serous meningitis, in which the eosinophile cells were normal or increased in number. In six of the tuberculous cases the large lymphocytes and transitionals were increased in number—namely, in Nos. 2, 3, 5, 6, 9, and 10, and in one of these they formed 23 per cent. of the total leucocyte count (No. 2). Very few differential leucocyte counts have been reported in tuberculous meningitis, but in those which I have found recorded a diminution or absence of the eosinophile cells was the rule.[13]

Granted, then, that in tuberculous meningitis there is usually no leucocytosis, have we any satisfactory explanation as to why such should be the case? There are, I think, four possible explanations. Firstly, the tubercle bacillus may enter the body and exert its characteristic effects without influencing in any way the number of leucocytes in the circulating blood. We know that the number of leucocytes in the blood is not the same for every individual but varies according to the robustness or delicacy of the person's constitution; thus in the robust it is relatively high, whilst in the feeble it is low, sometimes reaching as low a number as 3000 per cubic millimetre.[14] Other things being equal, one may therefore assume that persons with a low leucocyte count are more

* In the above list of cases the blood was taken from the patients shortly before or after a meal, so as to reduce to a minimum errors due to the effect of digestion on the composition of the blood. In no case was there any excessive drain on the blood, such as severe vomiting or diarrhœa.

liable to infectious diseases of all kinds than their more robust companions. On this supposition there is no direct connexion between the occurence of tuberculous disease and the leucocyte count, both being the result of a common cause—namely, depressed vitality. Secondly, there may be no leucocytosis because the irritation of the tissues by the tubercle bacillus and its toxins is either too mild in nature or too severe. In support of this we have experimental evidence; thus, if in an animal a dose of bacterial products of sufficient strength or large enough in quantity to cause death be injected, no leucocytosis occurs; to obtain a leucocytosis the dose [illegible] and the resistance of [illegible] dence that the toxic p[illegible] very mild nature; on the contrary, the exact opposite is the case, as evidenced by the effects produced by injection of tuberculin. For reasons, however, which will be discussed later, there is evidence to show that the most active constituent of the tubercle toxin can be taken up by the body tissues in very small quantities only and, such being the case, the irritation is insufficient to cause a leucocytosis (one of the signs of reaction of the body to an irritant). Thirdly, the tissues being constantly exposed to the toxins of the tubercle bacillus may in time come to be endowed with a relative immunity to them and therefore will no longer exhibit any reaction on further exposure to the irritant. Since every case of tuberculous meningitis is secondary to a deposit of tubercle in some other part of the body one may justly assume that during the time that elapses between the dates of primary infection and the onset of secondary disease in the cerebral meninges a continual absorption of tubercle toxin has been going on and although at the time of primary infection the irritant effect of the toxin may manifest itself in the usual manner, yet by a constant exposure to the poisons the body has so accommodated itself that a reaction in the form of a leucocytosis now no longer occurs, even when a general [illegible]bercle takes place. Fourthly, the most [illegible] toxin produced by the tubercle bacillus [illegible]ody of the bacillus itself but owing to the nature of the bacterial cell is unable to escape in sufficient quantities to exert its irritant action on the body tissues. All pathogenic organisms produce as a result of their growth extracellular toxins; some, however, such as the diphtheria, tetanus, and tubercle bacilli, also form intracellular toxins. Now the composition of the cell bodies of the diphtheria and tetanus bacilli is such that no great opposition is offered to the escape of any intracellular toxin which may be formed; this on being absorbed gives rise to a leucocytosis, the usual condition found in cases of diphtheria and tetanus. On the other hand, the tubercle bacillus being composed of various insoluble fatty acids any intracellular toxin formed can either not escape at all or can escape in very small quantities only unless the bacilli die in large numbers, when the intracellular toxins are diffused into the surrounding tissues and can then be readily absorbed. If tubercle cultures be filtered germ free and the filtrate be injected into an animal a less marked reaction occurs than if the bacilli as well as the filtrate be injected (some say this is due to the filtrate containing a toxalbumin having a temperature-lowering effect); this seems to favour the view that the intracellular toxins of the bacillus are more active than the extracellular. A patient, then, having become infected with the tubercle bacillus, there are produced at the seat of invasion extracellular toxin which has very little irritant effect on the tissues and intracellular toxin; the latter, however, is taken up by the body in such small quantities that the irritation produced is negligible and a reaction in the form of a leucocytosis does not appear.

Regarding the second finding in my cases—namely, a diminution in the number of eosinophile cells—we have no adequate explanation, the function of these cells being at present but imperfectly understood. Some observers consider that they are concerned with the defence of the body against invading micro-organisms, the granules of the protoplasm being secreted by the cells themselves and consisting of a substance which is injurious to bacteria. This view is supported by the fact that either finely granular oxyphil cells or coarsely granular (eosinophiles) are generally the first to arrive at the seat of invasion by a micro-organism.[15] Kanthack and Hardy,[16] however, state that in the case of the rat, the frog, or the guinea-pig, the coarsely granular oxyphil cells are never phagocytic. From these conflicting statements it is therefore evident that we are still far from knowing what the function of these cells is and any attempt to explain an increase or a diminution of them would be unwarrantable. The large lymphocytes and transitional forms being, as is well known, intensely phagocytic in nature their increase is most probably due to an attempt on the part of the body to rid itself of the offending agent—namely, the tubercle bacillus.

The conclusions to be drawn from the results of my investigations are that in tuberculous meningitis in children, (1) the red corpuscles are usually present in normal or increased numbers; (2) the majority of cases show no leucocytosis; (3) the eosinophile cells are reduced in number; and (4) the large lymphocytes and transitional cells are generally present in increased proportions.

For permission to make use of the cases in the wards of the North-Eastern Children's Hospital I am indebted to Dr. W. A. Wills, Dr. J. Taylor, Dr. J. Porter Parkinson, and Dr. G. Carpenter, and for access to the clinical notes of the cases my thanks are due to the house physicians, Mr. S. L. Harke, Mr. R. M. Im Thurn, and Dr. R. G. Nothwanger.

Colchester.

TWO CASES OF TRICHROMIC VISION.[1]

BY F. W. EDRIDGE-GREEN, M.D. DURH.,
F.R.C.S. ENG.

CASE 1.—One case (Professor J. J. Thomson) sees only three colours in the bright spectrum—red, green, and violet. He can distinguish nothing of the nature of pure yellow, like the sensation given him by the sodium flame in the spectrum. There is no definite colour to him at the portion of the spectrum where the normal sighted see pure blue. Reddish-green would describe the orange and yellow regions and greenish-violet the blue. λ 5950 (orange-yellow) is the point which differs most from red and green. There was no shortening of either end of the spectrum. The point of junction of the red and green differed somewhat in repeating the observations because of his great sensitiveness to simultaneous contrast. It was, however, always in the orange or orange-yellow, never in the yellow of the normal sighted.

Difference of hue perception.—I then tested him with my apparatus for ascertaining the size of different parts of the spectrum which appear monochromatic and found that he was defective in distinguishing differences of hue. A portion of the spectrum corresponding to the D lines and isolated by two shutters in the eye-piece of the spectroscope was first shown. The shutter on the red side was gradually opened until a difference of hue was seen. The monochromatic patch extended from λ 5889 to λ 6052, being exactly half as large again as that of the normal sighted, which occupies the space from λ 5889 to λ 5998. The monochromatic patch he called greenish-yellow. His monochromatic patch in the centre of the green bore exactly the same proportion to mine as in the case of the orange-yellow, being just half as large again.

Colour mixtures.—He was then tested with Rayleigh's apparatus for matching spectral yellow by a mixture of red and green. 0 of the scale corresponded to pure red, and 25 or 90° to pure green. He made the following 10 matches:—

Match.	Difference.	Match.	Difference.
†1. 13·40	+ 0·67	* 6. 11·75	− 0·98
*2. 12·0	− 0·73	* 7. 11·75	− 0·98
†3. 12·75	+ 0 02	8. 13·50	+ 0·77
*4. 12 0	− 0·73	† 9. 12·90	+ 0 17
†5. 13·50	+ 0·77	*10. 13·75	+ 1·02

Average, 12 73. Average difference, 0·684.

I find that my colour vision agrees with that of the large majority of persons and may therefore be regarded as normal. I made the following ten observations for comparison with those given above:—

Match.	Difference.	Match.	Difference.
*1. 11 0	+0·629	* 6. 10 0	−0·371
†2. 10·25	−0·121	† 7. 10·50	+0·129
*3. 9·80	−0·571	* 8. 10 50	+0·129
†4. 10·33	−0 041	† 9. 10 60	+0·229
†5. 10·33	−0 041	*10. 10·40	+0 029

Average, 10·371. Average difference, 0 229.

* Red shown first in the mixed colour. † Green shown first.

My match appeared to him bright-red and bright-green, the yellow appearing as green. The match appeared more correct through a pin-hole. The mixed colour of his match always appeared green to me. It will be noticed that his average difference is very nearly three times the amount of mine. On comparing the differences, according to the colour which was shown first, it will be found that these were all positive when the green was shown first and four out of the five were negative when he commenced with the red.

Green first	+ 0·67	Red first	− 0·73
	+ 0 02		− 0·73
	+ 0·77		− 0 98
	+ 0 77		− 0 98
	+ 0·17		+ 1·02
Average,	0 48	Average,	0 888

Below I give my differences for comparison.

Green first	− 0·121	Red first	+ 0 629
	− 0 041		− 0 571
	− 0·041		− 0·371
	+ 0·129		+ 0·129
	+ 0 229		+ 0 029
Average,	0·1122	Average,	0·3458

He seemed to get very easily fatigued with colours.

Classification test.—Called 1 (orange) "reddish-orange" and matched it with orange and dark yellows. Described 2 (violet) as mauve and put with it violets and purples. Named 3 (red) correctly and picked out various reds to go with it. Called 4 (blue-green) "green" and matched it with some greens. Only a few colours were selected in each case. On being asked to pick out all the yellows he chose those with orange in them. He regarded orange-yellow as his yellow and rejected pure yellows because he said that they had green in them. He had considerable difficulty in matching the colours. In common with the cases I have previously observed the effects of simultaneous contrast were much more marked than in the normal sighted. Two wools changed colour to him on being contrasted when no change was evident to me. This was particularly noticeable when one of the contrasted colours was red, green, or violet, and the other, one of the intermediate and adjacent colours.

Lantern test.—He correctly named the red, green, and violet with and without the neutral glasses and saw them at the normal distance. He had difficulty with yellow and blue. He called pure yellow "greenish yellow." It will be noticed that the examination with the spectrum gives a key to the mistakes made.

---

[15] Lazarus-Barlow: Manual of Pathology, pp. 406 and 282.

[16] Kanthack and Hardy: Ibid.

[1] A paper read before the Royal Society. The research was made with the aid of an instrument purchased with a grant from the Government Grant fund.

CASE 2 —The other case is that of Mr P S Barlow, B Sc , a research student in the Cavendish Laboratory He sees three colours in the spectrum—red, green, and violet The red gradually passes into the green and red green would describe this region and green violet that of the blue He sees no yellow or blue in the spectrum When I put the pointer in the yellow he said it was in the green He gave λ 5892 three times out of four as the junction of the red and green, the fourth time λ 5950 Both are in the orange-yellow He selected λ 4800 (blue) as the point of union of the green and violet He was very sensitive to simultaneous contrast When shown the violet first he put the junction of the green and violet at λ 4861, when shown the green first at λ 4740 There was no shortening of either end of the spectrum

Difference of hue perception —He was tested in the same way as Professor Thomson He also called the orange-yellow patch "yellow green," and I had to increase the size of the patch until it was half as large again (λ 5889 to λ 6052) as that of the normal sighted before a difference was seen I examined him in the same way with the other colours of the spectrum and found that in every part he marked out a much larger monochromatic patch than the normal sighted

Colour mixtures —He was then tested with Rayleigh's apparatus On being shown my match he said that the yellow was green and the mixed colour salmon pink He said that the yellow of my match was too dark, and in order to make a match, as far as luminosity was concerned, he had to increase the brightness of the yellow No match was then possible to me He made the following 10 matches —

Match		Difference	Difference, red first	Difference, green first
* 1	15·66	−0·815	—	—
* 2	17·0	+0·525	—	—
† 3	16·90	+0·425	—	—
* 4	16·33	−0·145	—	—
† 5	17·40	+0·925	—	—
† 6	17·0	+0·525	−0·815	+0·425
* 7	16·0	−0·475	+0·525	+0·925
† 8	15·33	−1·145	−0·145	+0·525
* 9	15·80	−0·675	−0·475	−1·145
†10	17·33	+0·855	−0·675	+0·855
Average,	16·475	Average 0·651	Average, 0·527	Average, 0·775

* Red first † Green first

Lantern test —He called pure yellow "yellow green' and pure blue "blue green ' Dark blue he called purple The other colours he named correctly.

Classification test.—1 he designated "golden yellow ' and matched it with orange 2 he called "purple" and put with it violets and purples 3 he said was "crimson" and sorted out a few reds to go with it 4 he named "blue" and matched with greens and blues Many colours were omitted He called yellow "yellow green " He chose orange yellow for yellow He found great difficulty with blue and green Ladies have several times told him of mistakes in this respect On being shown 4 (blue green) a second time he said that it was "pure green without a trace of blue " Simultaneous contrast was very strongly marked

I use the term *trichromic* as a statement of the fact that persons having this vision see only three colours in the bright spectrum, whilst the normal sighted see six and may, therefore, be designated *hexachromic* It is probable that the appearance of the bright spectrum to the trichromic is very similar to that of a spectrum of feeble luminosity to the normal sighted in which only three colours—red, green, and violet—are seen The defective difference perception which is found in these cases accounts for most of the facts Both these cases are bordering on the tetrachromic, as the sodium flame appears to give rise to a distinct sensation

Cambridge

OBSERVATIONS UPON THE BLOOD [1]

BY C WILLETT CUNNINGTON, M B , B C CANTAB

MUCH attention is rightly paid nowadays to the condition of the blood for purposes of diagnosis and prognosis Although a vast mass of information has already been recorded by many observers, yet much work remains to be done In this paper chief attention will be paid to points hitherto neglected The question of the granularity of the eosinophile cell has not been touched upon so far as I am aware, yet it is of considerable importance and it would be interesting if others directed their attention to this with a view to confirming or correcting my results Further work requires to be done on the blood in those obscure conditions of "abdominal pain associated with pyrexia" where the diagnosis is uncertain Some other conditions of the blood will be briefly referred to

The granularity of the eosinophile cell —In order to count the number of granules in these cells it is necessary to use a high degree of magnification A Zeiss $\frac{1}{12}$ objective, oc 5, tube length 160 millimetres, was employed Even with this magnification (nearly 1200 diameters) the smallness of the granules entailed considerable eye strain Furthermore, the granules in many of the cells are uncountable as they are so crowded together Suitable cells must be carefully sought for, "crowded" ones being rejected An average of the counts obtained in each specimen may be considered as a fairly accurate estimation of the granularity of the cell for that particular specimen of blood The first question that arises is whether the number of granules is at all constant in the blood of health, and next whether the granularity is constant or varies with different people This was the first point to be settled Briefly, it was found that the granularity of the eosinophile was almost the same for all healthy adults , each cell contains from 210 to 220 granules , during health the limits of variation are narrow This being settled the blood in various diseases was examined In most acute diseases it is well known that the (coarsely granular) eosinophile cell is diminished and may entirely disappear On its reappearance marked changes in the granularity are seen The cell is no longer uniform , it reappears in two forms , the commoner form is smaller than normal and has a considerably diminished granularity Thus, from 100 to 120 granules per cell is the common figure

The second variety of cell is larger, the nucleus perhaps more spherical, and the number of granules greatly increased These "megaleosins," as they may conveniently be termed, generally have from 250 to 350 granules per cell The granules themselves are larger, I think, than those in the "microeosins," but it is difficult to assert this definitely If during recovery from almost any acute illness the blood be examined from time to time it will be seen that the small celled variety (which may be called "microeosins") increases gradually in granularity, while the "megaleosins" disappear, until ultimately the normal conditions are resumed

Reference to some cases may be made in proof of these statements A case of syphilitic psoriasis where eosinophilia was present (11·6 per cent) showed a diminished granularity (120 granules per cell) In typhoid fever, where the eosinophile cell is generally late in returning to the peripheral blood, the granularity is at first from 140 to 150 Slowly this increases during recovery in one case the normal figure was only reached three weeks after the temperature became normal In lobar pneumonia, where the cell returns rapidly after the crisis, the granularity at first is below this figure—namely, from 120 to 130 Indeed, most of the lowest figures were obtained in cases of pneumonia about the time of crisis In some cases where a disease is acute and terminates rapidly—e g , a slight attack of appendicitis lasting a couple of days—the granularity of the eosinophile increases during convalescence until it exceeds the normal After a few days the figures diminish again to normal in a manner resembling a temperature chart where the line falls below the normal for a few days after an acute fever

Much more work has to be done upon the granularity of the eosinophile cell before definite conclusions can be safely made At present, however, I cannot help connecting the suggestions afforded by these notes with the hypothesis of the function of this cell—namely, that the granules are antitoxic or bactericidal in nature, that they are discharged into the blood at the onset of an infection and that after the toxins have been neutralised the blood becomes richer in antibodies The manner in which the granules steadily increase in number during convalescence certainly suggests that of a gland cell and its method of secretion

as "abdominal influenza," [illegible] tion," often not diagnosed at all Supposing a patient is seen with pain over the abdominal area (not localised) associated with two or three degrees of fever, if it is a hospital case, it is easy to anticipate the diagnosis that will be made. The physician murmurs "enteritis," the gynæcologist talks of "salpingitis," while the surgeon whips out the appendix. Will a blood examination help these seekers after truth? The more experience one has on blood counts in these obscure cases the more one realises that the answer is in the negative.

---

[1] An abstract from the thesis for the degree of M B Cantab

A surgeon has been heard to state that a leucocytosis of over 20,000 "means pus." A glance at any collection of statistics shows the inaccuracy of such a remark. Three or four days' constipation may send the white count up to the "pus level." Woe betide your appendix if you enter an up-to-date surgical ward with a loaded cæcum! Of course, great value is rightly attached to a *series* of blood counts upon any one patient. This point is so well recognised now that it is unnecessary to discuss it further. I would suggest, however, that consideration of the percentage of the coarsely granular eosinophile cell in these cases is often helpful.

To summarise my results, it may be briefly stated that when this cell is present to the extent of 1 per cent. or more it is almost certain that there is no active suppuration taking place. This cell may be quite absent although there is no abscess. In some cases of abscess there is no leucocytosis but in these cases the eosinophile cell is always greatly diminished in percentage and is generally absent. Cases of chronic pyosalpinx frequently show no leucocytosis, yet the eosinophile percentage is very small, thus differing from cases of ovarian tumours. It is often asked, Why do some cases of suppuration give a leucocytosis and others not? Briefly the answer is that when toxins are being absorbed under pressure there is a high leucocytosis; when the fibrous wall of the abscess is so dense that very little absorption of toxins is taking place there is little or no leucocytosis; when pus is draining freely away the same absence of leucocytosis is found. But in both of these two conditions (conditions of suppuration without leucocytosis) the eosinophile cell is greatly diminished or absent. Hence the importance of paying attention to the *differential* as well as the *simple* blood count.

Secondary pernicious anæmia.—A man, aged 48 years, was seen in August, 1903, suffering from a moderate attack of purpura hæmorrhagica. The blood count showed 4,216,000 red cells and 1500 white cells per cubic millimetre. A differential count showed: finely granular eosinophiles, 50·5 per cent.; coarsely granular eosinophiles, 1·5 per cent.; lymphocytes, 47 per cent.; and hyalines, 1 per cent. There were no abnormal white cells or red cells. Eight months later, after one or two slight attacks of purpura, his blood count was as follows: red cells, 1,900,000 and white cells 3500 per cubic millimetre; hæmoglobin, 45 per cent. A differential count showed: finely granular eosinophiles, 41·4 per cent.; coarsely granular eosinophiles, 0·0 per cent.; lymphocytes, 52·4 per cent.; hyalines, 6·1 per cent.; myelocytes, 0·2 per cent.; and nucleated red cells, 770 per cubic millimetre (chiefly normoblasts, a few megaloblasts). The colour index was 1·1. There was marked poikilocytosis. In other words, the blood was typical of pernicious anæmia. At the necropsy the usual changes of pernicious anæmia were found.

The point of interest in this case is this. Was the intense anæmia secondary to the repeated hæmorrhages or was it true pernicious anæmia in which the hæmorrhages began before the characteristic blood changes? This case suggests that anæmia gravis is not always a primary disease. One wonders, indeed, is it ever? It is generally stated that the cardinal blood changes in pernicious anæmia are low red count, high colour index, poikilocytosis, presence of nucleated red cells, and generally myelocytes. Now if a number of cases of chronic anæmia, secondary to hæmorrhages or malignant disease, phthisis, &c., rickets, scurvy rickets, or dyspepsia, are examined, one loses much faith in "cardinal signs." One finds an anæmic patients with red cells under 3,000,000 per cubic millimetre, poikilocytosis, nucleated red cells, and *low* colour index, and this persists for months and months. Or a patient may have all the changes mentioned except the presence of nucleated red cells and one watches and waits until the complete set of signs appear. Are these "pernicious anæmias"? Are they on the border-line? Later, when all the signs are found, have they passed the line? The more one sees of such puzzling cases the more one hesitates to employ the term "primary pernicious anæmia."

Highbury-hill, N.

TETANUS AND CHLORAL HYDRATE.

BY JOHN MABERLY, M.R.C.S. ENG., L.R.C.P. LOND.

IN reading the reports of cases of tetanus we are usually struck with the number of drugs (including antitetanic serum) which have been administered and consequently it is quite impossible to decide which drug had the chief influence in curing the disease. The following case, however, stands on a different basis, the only antitetanic drug given being chloral hydrate. It is therefore possible to form some estimate of the action of that drug on the disease and on this account the record may be of some value in throwing light on the subject and in affording a suggestion for the treatment of tetanus in the future.

The patient, a powerfully built man, 21 years of age, was brought to me by Mr. P. B. T. Stubbs of Wynberg on May 27th, 1904, at about 11 A.M., suffering from violent abdominal pain. He was sent to the Woodstock Hospital where on examination we found a board-like hardness of the muscles of the abdomen with a tender spot at about the centre of the right hypochondriac region; pressure over this spot brought on tonic spasms which extended thence over the whole body. Neither trismus nor opisthotonos was very marked. The history elicited was that 48 hours prior to the attack the patient had been in his usual robust health; he then began to feel ill and about 18 hours prior to admission to hospital had severe rigors and abdominal pains followed by muscular spasms which rapidly became very severe and painful. There was no history of injury and, with the exception of one or two thorn scratches on the hand, there was no mark of any. The only possible diagnosis was that of tetanus, the poison having probably been conveyed into the system by one of the natural orifices. The temperature was 97·4° F. and the pulse-rate was 86. The patient was ordered 20-grain doses of chloral hydrate by the mouth every three hours. This had not the slightest effect, the spasms becoming more frequent and severe. At 6 P.M. a further consultation was held in which Dr. Casalis joined; the latter agreed in the diagnosis and we decided to increase the doses of chloral hydrate to 60 grains every four hours. The first dose was administered by the mouth in the form of six drachms of the B.P. syrup of chloral with half an ounce of brandy. This dose was immediately preceded and followed by a most violent tetanic spasm, accompanied by marked opisthotonos. The dose was repeated at 9 P.M., at 1 A.M., and at 5 A.M., the last two doses being given per rectum. In 11 hours 240 grains of chloral were administered. With the exception of the one immediately after the first dose of 60 grains no spasms occurred, the patient slept for about seven hours, his pulse remained steady at 88, and the temperature at about 98·6°. 25 ounces of urine were drawn off by catheter at midnight; the first portion was blood-stained. At 8 A.M. on the 28th the patient appeared to be well under the influence of chloral and I gave orders to stop the administration of the drug until the spasms reappeared. At 12.30 P.M. 18 ounces of clear urine were drawn off and a slight spasm occurred. Milk and hot water administered by the mouth were mostly returned and rectal feeding was adopted. The bowels were slightly opened after a soap-and-water enema. At 4 P.M.—i.e., 11 hours after the last dose of chloral—a severe tetanic spasm occurred; 60 grains of chloral hydrate were administered by the rectum; some slight spasms occurred after this. At 10 P.M. a dose of 40 grains of chloral was given and this dose was repeated every four hours till 6 A.M. on the 29th; the dose was then reduced to 30 grains given at 2 P.M. and at 6 P.M. No spasms had occurred for 18 hours and the administration of the drug was again discontinued. Two doses of one minim each of croton oil in a little butter were given during the night, with the result that the bowels were well opened with the assistance of an enema on the morning of the 29th. At 4 A.M. on the 30th a slight spasm occurred and 30 grains of chloral were administered. Another spasm occurred at 11.30 A.M. and the dose was repeated. At 5.30 P.M. the last spasm occurred and the last dose of 30 grains of chloral was given. The patient complained of feeling sore all over and was for the first time really conscious. He had no recollection of anything since the afternoon of May 26th, a period of rather more than four days, although during the greater part of the time he appeared to be partially conscious. He made a rapid recovery, his only trouble being inability at first to pass urine without the assistance of the catheter and a tendency to constipation. These symptoms subsided and he returned home on June 3rd in perfect health. His illness lasted altogether about 10 days.

During the last few years the discoveries of bacteriologists, particularly with regard to antitoxic sera, have at times threatened to revolutionise certain branches of medicine and have induced a tendency among medical men to put aside some of our old and well-tried therapeutic agents in the hope of replacing them by more scientific substitutes. The use of chloral hydrate in tetanus is, I think, a case in point. Anti-tetanic serum has not in practice realised the hopes raised in its favour by laboratory experiments and the result of this case induces me to put in a plea on behalf of the drug which in this instance, at any rate, proved equal to the task of controlling the symptoms and arresting the disease.

I am not aware of any records in which such large doses as [illegible] en given every four [illegible] ed within 11 hours [illegible] either the temperature or pulse. In the normal condition of the system such an enormous quantity taken in the same time would surely produce a fatal result, the evident explanation of a contrary effect in this case being that the system under the influence of the tetanic poison is capable of bearing enormous doses without any ill-effect, provided, of course, that one can draw any definite conclusion from a single case. In other words, chloral hydrate and the poison of tetanus are directly antidotal a[illegible] er work carried out [illegible] ssertion. In order to [illegible] of commencing the [illegible] by doses of about 30 or 40 grains of chloral hydrate and steadily increasing this to a drachm or more until the desired effect was produced, repeating the dose when the spasms recurred, and gradually reducing the quantity as the spasms became less violent in character. In this particular instance 20-grain doses had not the least effect, but 60 grains completely controlled the symptoms. It was possibly a favourable case for treatment, but it at any rate demonstrated the fact that chloral hydrate is a very antitetanic remedy and one well worth further investigation on the lines suggested.

Woodstock, Cape Colony.

THE THERAPEUTICS OF ASPIRIN AND MESOTAN.[1]

BY JAMES BURNET, M.A., M.B., B.CH. EDIN., M.R.C.P. EDIN.,

[illegible]

EDINBURGH.

IT was in March, 1876, that is, nearly 30 years ago, that the late Dr. T. J. Maclagan contributed to THE LANCET a paper, entitled "The Treatment of Acute Rheumatism by Salicin." The opening sentences of that paper I may be allowed to quote, as they are historically interesting: "In the course of an investigation into the causation and pathology of acute febrile ailments, which have for some time engaged my attention, I was led to give some consideration to intermittent and to rheumatic fever. The more I studied these ailments the more was I struck with the points of analogy which existed between them. On a detailed consideration of these I shall not now enter, suffice it to say that they were sufficiently marked to lead me to regard rheumatic fever as being, in its pathology, more closely allied to intermittent fever than to any other disease, an opinion which further reflection and extended experience have served only to strengthen."

[illegible] ta[illegible] m[illegible] or [illegible] as they are [illegible] being employed in every case. The series of these compounds is a large one, its basis being the radicle salicyl ($C_7H_5O_2$). Salicin itself has the formula $C_{13}H_{18}O_7$, while that of salicylic acid is $C_7H_6O_3$. Salicylate of sodium, a remedy which has to a large extent replaced both salicin and salicylic acid, has a complicated chemical formula, represented by $(NaC_7H_5O_3)_2H_2O$. Methyl salicylate, or oil of winter-green, possesses the formula $CH_3C_7H_5O_3$. Salol, another member of this group, is the phenyl ether of salicylic acid. The preparations named are the more familiar of the salicyl compounds. To-day, however, I am able to speak of two newer remedies belonging to this series—viz., aspirin and mesotan, both of which have been introduced with a view of replacing those already mentioned. Aspirin is the acetic ester, while mesotan is the methoxymethylester of salicylic acid. I shall now give a brief account of these two preparations in order to show their value in the treatment of disease and more especially in their application to rheumatism and rheumatic affections.

Aspirin, as I have already stated, is the acetic ester of salicylic acid; in other words, it is a combination of acetic and salicylic acids. It occurs in the form of fine white acicular crystals, possessing a distinctly acid odour and an agreeable acid taste. It is soluble to the extent of 1 per cent. in water at 37° C., while it is easily soluble in alcohol and in ether. Dilute alkaline solutions also readily dissolve it, splitting it up into its component parts, a matter of considerable practical importance and one to which I shall have again to refer. It is only slightly soluble in an acid medium. When, therefore, it is taken into the stomach the salicylic acid is not liberated; in fact, it is not until this compound reaches the intestinal canal that it becomes split up and the salicylic acid is set free. Aspirin differs chiefly from other salicyl compounds in that it is much less irritating to the gastric mucous membrane. It has been found experimentally that it takes at least two hours for artificial gastric juices to liberate even a minute quantity of salicylic acid from aspirin, but as it is not the least likely that an ordinary dose would remain for this length of time in the stomach we can readily understand that, generally speaking, this compound does not produce the gastric discomfort so often experienced after taking a dose of salicylic acid or of sodium salicylate. In the intestinal canal, however, the disintegration of aspirin is effected very rapidly, the salicylic acid entering into its composition being there set free. According to certain observers the elimination of aspirin takes place much more slowly than that of sodium salicylate and consequently its salicylic acid component circulates for a longer period in the blood than does an equal amount of salicylate. Again, it has been proved by experiment that whereas salicylate of sodium acts as a cardiac depressant aspirin tends to increase the heart's activity. Another point of distinction is that tinnitus aurium, which so frequently occurs during the administration of sodium salicylate, is rarely if ever met with when aspirin is administered. This is probably due to the difference in the rate of absorption of the two remedies. In the case of the former the salicylic acid is absorbed very rapidly, so that the circulation becomes suddenly affected thereby, whereas in the case of aspirin absorption of the salicylic acid takes place more gradually. It would appear that the liberation and elimination of the salicylic acid contained in aspirin take place with considerable rapidity, as in many cases we have been able to detect its presence by the ferric perchloride test within an hour after an ordinary dose had been administered. Another interesting fact regarding aspirin is that it produces an increased excretion of uric acid.

I have already referred to the fact that in presence of dilute alkalies aspirin becomes rapidly disintegrated. Too much importance cannot be attached to this matter as I have time and again found medical men prescribing it in combination with bicarbonate of potash. The result of doing so is to liberate the salicylic acid almost as soon as the powder enters the stomach, with the disastrous effect of producing considerable gastric irritation and discomfort. Personally I have been in the habit of giving it suspended in a glass of lemon water. It may, however, be placed dry on the tongue, or administered in cachets, or in wafer papers. I would particularly warn against prescribing it in tablet form, as not only do the patients thereby get to know what they are taking but one can never be certain when a tablet may dissolve, and there is consequently a risk lest the dissolution of two or three tablets may take place at once, an occurrence which might not prove advantageous to the patient.

---

[1] A paper read before the Therapeutical Society on March 28th, 1905.

In a few cases I have given it in *cold* milk and have found, especially in the case of children, that this method of administration was distinctly beneficial. Hot fluids, of course, must be avoided, as these as well as moisture tend to decompose the drug.

As regards the dosage of aspirin little need be said. The average single adult dose is from 10 to 15 grains. In cases where its administration requires to be frequently repeated the dose ranges from five to ten grains, although a larger amount may be given at frequent intervals in certain cases. To children I usually give from three to five grains, but in many instances I have given as much as ten grains without any bad effects and with considerable benefit to the patient.

I shall now consider the therapeutic indications for the administration of aspirin. It is in rheumatism and rheumatic affections that this remedy is more especially to be employed. Personally I have prescribed this preparation to over 200 adults suffering from rheumatism in one or other of its varying manifestations. Regarding my employment of this remedy in acute rheumatism I can speak in terms of the highest praise. When a patient is seen at the outset with a temperature of 103° F., swollen joints, and profuse sour-smelling sweat he is at once put between blankets and the affected joints are wrapped up in cotton-wool. Aspirin in 10 to 15 grain doses is then given every four hours. Within three days the temperature in almost every case becomes normal. The drug is then administered thrice daily for a week longer and then a dose varying from five to ten grains is given for the next three weeks. Experience has shown that if we stop the administration too soon or give the drug in too small doses a relapse is almost certain to take place. My practice of late has accordingly been to push the drug and almost invariably I have given it in lemon-water. In particular I have found that when the patient is in bed and between blankets very copious perspiration results from a half to one hour after the first dose has been given and the temperature is thereby reduced. When, however, aspirin is given to patients who are going about there is not nearly the same tendency to sweating. There can be little doubt that the amount of sweating produced is apt to prove extremely disagreeable to the patient, as the clothing and blankets soon become wet just as if they had been wrung out of water. To counterbalance this, however, the almost immediate relief from pain which the patient experiences is highly satisfactory. In chronic rheumatic affections aspirin also acts well and many cases of lumbago and pleurodynia are benefited by its use.

I have had considerable experience of the value of aspirin in the treatment of rheumatic affections of childhood and I shall now refer to its employment in this connexion at somewhat greater length. It is now four years ago since I began to employ aspirin in the treatment of chorea, which may be taken as a rheumatic condition in practically every case. The first case of chorea which I treated with aspirin was that of a girl, aged 13 years. She had been under treatment previously for the same condition. She was small for her age and had a definite history of acute rheumatism. There were well-marked mitral presystolic and systolic murmurs, while the heart was considerably enlarged. She was, moreover, very anæmic. It was considered advisable to keep her in bed and to put her on iron and digitalis, as she suffered considerably from breathlessness. Under this treatment she improved slightly but at the end of a month I could not pronounce her condition as being at all satisfactory. Accordingly the iron and digitalis were stopped and instead I ordered ten grains of aspirin to be given every four hours. She began almost immediately to improve, so that in three weeks' time she was comparatively well and in two months she was completely restored to health. Even the anæmia was scarcely perceptible, although the cardiac murmurs still remained. This case naturally impressed me and since then I have treated several cases of chorea successfully by means of aspirin. Arsenic, which is usually given in this disease, is no doubt beneficial in many cases but it has been known to fail. I have yet to meet with a case of chorea in which aspirin, given in suitable doses, failed to bring about alleviation of the patient's condition. It must be distinctly borne in mind, however, that if this remedy is to do any good it must be given in fairly large doses, say from 10 even up to 15 grains. Children, as a rule, take it well and I have never yet found it to produce anything like toxic symptoms. I am quite prepared to admit that it is exceedingly hazardous to maintain that chorea may be cured by the administration of any particular drug; still, I consider that aspirin has a powerful influence over this disease, more so indeed than any other single remedy with which I am acquainted.

In the acute rheumatism of childhood I have likewise obtained good results from the use of aspirin. I have given it in from five- to ten-grain doses every three or four hours and have found that the temperature was thereby rapidly reduced and the symptoms were greatly alleviated. I have especially found the value of aspirin displayed in cases of acute sore-throat of rheumatic origin, so often met with in children. I believe that pharyngitis is one of the commonest manifestations of acute rheumatism in childhood and have frequently observed children who complain of nothing save sore-throat develop in a day or two other more characteristic manifestations of rheumatism. Further, I maintain that many cases of tonsillitis attended, as these so often are, by malaise and a general soreness all over the body are in reality examples of acute rheumatism, quite as important from a therapeutic point of view as an arthritic attack. It is, however, always a matter of difficulty when we find a child suffering from acute sore-throat to say whether the case is a simple or a rheumatic one. That many of these attacks yield to anti-rheumatic remedies is to my mind a matter of considerable importance in settling this question. In such cases aspirin proves of great value. I have known patients with a temperature of from 102° to 103° F. obtain relief within 24 hours from the administration of frequently repeated doses, varying from five to ten grains, of this remedy. At the same time, moreover, the local condition improves, even when no application has been made to the throat, although as a rule some glycerine pigment will be found a helpful adjunct to the internal treatment.

Children not infrequently suffer from rheumatic torticollis, which is a very painful affection. Aspirin will be found of the greatest possible service in this condition. So, too, I have found it helpful in the treatment of certain cases which I have ventured to term gastro-enteric spasm. In this condition the patient complains of acute gastric pain after a meal and has an urgent call to stool. These cases are certainly not all rheumatic in origin but many of them undoubtedly are, and in some of these aspirin has a decidedly curative effect. There is, again, no remedy so useful as aspirin in the so-called growing pains of childhood. No doubt salicylate of soda acts well in such cases but it is usually badly taken by children and tends to upset the stomach, whereas aspirin has no such tendency and moreover is more pleasant of administration. In the psoriasis of childhood, which I have always maintained to be of rheumatic origin, I have time and again proved the marked success attending the administration of aspirin in full doses. Small doses are valueless and only failure will result if the remedy is not given in from 10 to 15 grain doses thrice daily.

Regarding the use of aspirin in rheumatic eye affections I personally speak with considerable diffidence as I have only treated two cases altogether, one being a rheumatic iritis and the other a conjunctivitis occurring in a rheumatic subject. Fortunately, however, for my present purpose we have testimony as to its efficacy from authorities much more able to speak on this subject than I am. Thus, Frank[2] of New York has recorded his successful experience of the treatment of rheumatic iritis by means of aspirin which he administered in eight-grain doses four times a day, combining it with the external application of mesotan to the part of the face immediately bordering on the affected eye. Again, Neustatter[3] of Munich speaks highly of this remedy in ophthalmic practice after its employment for more than two years. He finds it of value in iritis, episcleritis, and certain other conditions. In the majority of these cases it has a favourable influence on the morbid processes not only indirectly but also directly by curtailing the duration of the disease and contributing to the more speedy removal of the severer symptoms. He asserts that aspirin acts in these cases as an analgesic, while in some it seems to produce an hypnotic effect as well.

Although aspirin undoubtedly finds its chief indication in rheumatism and rheumatic affections it has been employed with more or less success in certain other conditions. I must now briefly refer to these In this connexion I may specially mention its employment in the treatment of the hectic fever which forms so prominent a feature in cases of pulmonary tuberculosis I believe it was first used in this connexion by Renon[4] of Paris He administered aspirin in from seven and a half to fifteen grain doses between 12 noon and 5 P M *In three fourths of his cases he observed an immediate anti thermic effect* The temperature decreased by one two, and even three degrees in the afternoon, with a tendency to rise again in the evening towards 8 or 9 o clock The temperature, axillary or rectal, gave a diagram inverse to the normal type with a maximum rise in the morning When, however, the drug was discontinued the temperature rose nearly always to the high degree it showed before its use I have been able to investigate the action of aspirin on the temperature of tuberculous patients Thus, in a case of abdominal tuberculosis I gave aspirin in five grain doses every four hours and found that so long as its administration was kept up I could rely pretty confidently on controlling the temperature No excessive perspiration ever took place, nor was I able to detect salicylic acid in the urine although it was carefully looked for every day I also tried the effect of aspirin in reducing the temperature of pulmonary cases In every instance when it was given in five grain doses every four hours the temperature was reduced by one or two degrees, but in no case can I say that I was able to effect a return to the normal by the use of aspirin alone One fact I learned from the employment of aspirin in this connexion—viz , that small doses frequently repeated do not, as a rule, produce the excessive perspiration which large single doses bring about especially when the patient is in bed between blankets I cannot, however say that any real advantage results from the employment of aspirin in cases of tuberculosis

---

[3] Munchener Medicinische Wochenschrift, 1903, No. 42.

I shall now refer to the use of aspirin as an analgesic in conditions other than rheumatic More especially on the continent it has been used successfully in alleviating the pain of uterine, rectal, and mammary cancer In such cases it proves most satisfactory when given in fairly large doses say 15 grains every four hours Again, in many cases of neuralgia it acts well and within the last few years it has found a considerable field of usefulness in dental practice Thus it has been administered with a view to alleviate the pain after the application of arsenic to the nerve in cases of carious teeth It is also said to be of service in the treatment of some varieties of toothache In all such cases it must be given in from 15 to 20 grain doses in order to achieve satisfactory results I have prescribed it in several cases of neuralgia with varying effect Practically speaking however, I find it specially suitable in cases of sciatica and in cases of supra orbital neuralgia I think I have also seen benefit follow its use in two cases of peripheral neuritis although in both of these hypodermics of strychnine were also employed In every case in which I obtained analgesia from the use of aspirin I never gave less than 15 grains at a single dose Its value in that form of influenza which is attended by myalgia is undoubted A dose of ten grains given three times a day will be found very serviceable, not only in alleviating the pain but also in reducing the temperature Its use has been suggested also in cases of pleurisy with effusion and no doubt the copious perspiration produced by its administration might be of value here

Lastly, I wish to say a word or two regarding the treatment of diabetes mellitus and glycosuria by means of aspirin Williamson[5] of Manchester has already written on this subject In 11 cases which were under careful observation for a long time, he obtained the following results —(1) in four very severe cases of diabetes aspirin did not produce any decided effect on the excretion of sugar (2) in three cases of chronic glycosuria the excretion of sugar ceased when aspirin was given the diet being kept unchanged , and (3) in four cases of diabetes mellitus of the milder form the excretion of sugar appeared clearly to be diminished by the aspirin The dose necessary to produce a decided diminution of the excretion of sugar he found to be 15 grains given from four to six times a day I have recently had one case of chronic glycosuria under my care and to this patient I gave 15 grains of aspirin four times a day, with the result that although he had been under treatment for this condition for a considerable time still without change of dietary I was able to reduce the amount of sugar excreted to a mere trace This to me is a significant proof of the value of aspirin in some of these cases at least

In conclusion, let me briefly summarise the advantages which aspirin appears to me to possess 1 If given in acidulated water it never produces any gastric disturbance, and *only* after the administration of large doses do we occasionally meet with untoward symptoms, such as tinnitus aurium 2 It does not de
produce any renal irritation
temperature more rapidly and
of soda 4 In doses of from 10 to 15 grains given to febrile patients who are in bed between blankets aspirin produces copious perspiration within half an hour This, however, does not result when the drug is taken in afebrile states and when the patient is going about nor does it result when doses of five grains are given, even if the patient is in bed 5 Aspirin is pleasant to take whereas salicylate of soda even when administered in cachets or in mixtures, is very liable to produce nausea The advantage of this is that aspirin can be tolerated for a longer period than can the salicylates In my opinion, therefore aspirin entirely replaces all the other salicyl compounds, as it is a more powerful analgesic and antithermic agent than any of the others, while at the same time it is readily taken and has no tendency to produce gastric disturbance

I shall now briefly refer to my experiences with mesotan[6] which as I have already indicated is the methoxy methyl ester of salicylic acid It is a pale yellowish fluid possessing very little odour and perfectly miscible with alcohol, ether and vegetable oils Until the introduction of mesotan oil of wintergreen was the salicyl compound most commonly employed for external application , the latter however possesses a disagreeable and penetrating odour Mesotan is readily absorbed by the skin and thus naturally produces a very rapid effect upon the underlying tissues Its absorption is proved by the fact that when the skin is examined after the application of mesotan to the cutaneous surface salicylic acid is found to be present Before use it should be diluted with an equal quantity of olive oil It should either be painted on the affected part with a brush or gently rubbed over the surface of the skin about a teaspoonful being used for a single application When rubbed over healthy skin a slight redness takes place accompanied by a warm sensation and an odour which is somewhat suggestive of oil of wintergreen but not by any means so pungent or disagreeable When an examination of the urine is made the presence of salicylic acid can be detected within an hour or less after the inunction

I have used mesotan in at least 100 cases and can therefore speak with some knowledge of its potency In patients suffering from acute articular rheumatism I have painted on a mixture of equal parts of mesotan and olive oil thrice daily After these applications the joints were not wrapped up in cotton wool nor was any other covering applied The result so far as the alleviation of the pain was concerned, manifested itself as a rule on the second day of treatment but there was practically no effect upon the temperature until aspirin was administered internally I wish particularly to point out that the wrapping up of the affected joints in this disease appears to be unnecessary when mesotan is used At all events in the case of the patients under my care the joints were left exposed and yet no bad effects followed I may also mention that in every case the salicylic reaction was obtained in the urine within two hours at the latest after the first application This fact proves that mesotan is absorbed even after simple painting of it over the cutaneous surface

In chronic articular rheumatism I have used a mixture of mesotan and olive oil which was directed to be well rubbed into the affected parts In one of these cases a slight amount of erythema appeared but on stopping the inunctions for a few days it completely vanished In the majority of instances more or less complete relief from pain and stiffness took place within three or four weeks although a few of the patients derived little or no benefit from the treatment We must, of course expect failures with every remedy and probably some of my cases in which mesotan failed to act may not have been rheumatic in origin at all

Of arthritis deformans I have only seen three cases recently In all of these mesotan inunctions afforded considerable relief but this unfortunately was only of a temporary nature , still it was found more beneficial than oil of wintergreen which had been previously employed in two of the cases. In this disease, however, we cannot look for an absolutely complete cure as the condition of the joint has become pathologically fixed, so to speak, and consequently alleviation of the attendant symptoms is all that we can expect. Mesotan, however, appears to possess a certain power of affording temporary relief to the pain which is present in these cases, and must therefore, I think, be regarded as a valuable adjunct to treatment.

---

[4] Bulletins et Memoires de la Société Medical des Hopitaux de Paris 1900 No 22

[5] Brit Med Jour Dec 27th 190[illegible]

[6] Its chemical formula is said to be $C_6H_4<{}^{OH}_{COO\ CH_2\ O\ CH_3}$ and it contains [illegible] per cent of salicylic acid

It is in cases of muscular rheumatism that I have had the most marked examples of success from the use of mesotan. I have prescribed it largely for lumbago and also for pleurodynia, as well as for other forms of muscular rheumatism. In most of these cases the mesotan and olive oil mixture was rubbed well over the affected part. In none of my cases was there any irritation of the skin produced and in a very small proportion was the result imperfect. Two cases of torticollis were completely cured within three days after vigorous applications of the oil to the neck. A somewhat disagreeable papular cruption made its appearance in one of my patients but it yielded readily to the application of a soothing ointment. Practically speaking, therefore, mesotan has afforded me uniform success in cases of muscular rheumatism. In fact, I regard it as a specific for such conditions and I much prefer it to internal medication or the application of liniments and of blisters.

Several cases of sore-throat of undoubted rheumatic origin yielded when mesotan was painted over the front of the neck. In some cases of acute pharyngitis and tonsillitis it proved unsuccessful and I have no doubt whatever that these were non-rheumatic. I am of opinion, therefore, that mesotan is a most valuable external application in those forms of sore-throat which occur in rheumatic subjects. It has been stated that mesotan is of no use in cases of sciatica; this, however, is not my experience, for though it has failed in some instances, in two more particularly it proved of the greatest possible service. I may mention that both of these patients had a very distinct rheumatic history. Two drachms of mesotan and olive oil were well rubbed in along the course of the nerve and after each inunction the patients always experienced marked relief; consequently I think mesotan is worthy of a trial in cases of sciatica where the patient is a rheumatic subject. Of five cases of acute pleurisy in which I employed mesotan externally not one obtained the slightest benefit. The oily mixture was either rubbed into the skin over the affected part or else painted on thrice daily for two or three days but no relief even of the pain was thereby afforded. It was in the hope that some of these cases might eventually prove to be rheumatic that I resorted to mesotan but in this expectation I was entirely disappointed. Facial neuralgia again is not in my experience a condition in which mesotan is of much service. None of my cases improved under its use, while one even asserted that the pain was always aggravated by it. Nor is it of any use in arthritis of gonorrhœal origin. I tried it experimentally in four cases of this kind and in no single instance did any result whatever follow its use.

My experience of mesotan, considerable as it has been, has afforded me valuable information as to its mode of employment and also as to the kind of case in which it may be expected to yield good results. I have no hesitation whatever in saying that it is in cases of muscular rheumatism that mesotan proves of most effect. True, it possesses a distinct value in other rheumatic conditions but not to the same extent and is then generally of use merely as an adjunct to internal remedies, such as aspirin.

A good deal has been written recently regarding the irritative effects which mesotan is apt to produce upon the skin. As I have seldom witnessed these perhaps I may be allowed to state what, in my humble opinion, are the causes which lead to cutaneous irritation when mesotan is employed. In the first place it should, as a general rule, be diluted with an equal part of olive oil before use. Then, again, the mixture should be merely painted over the area involved and not used as an inunction when the skin is at all sensitive or delicate. It is also advisable in most cases to apply the remedy to different portions of the affected area on each occasion and whenever any undue redness appears it is well to intermit its use altogether for a day or two. Moisture, it should be remembered, decomposes mesotan and its decomposition will undoubtedly lead to the appearance of skin eruptions. This, to my mind, is one of the principal causes for the complaints one sometimes hears regarding the so-called irritating properties of mesotan. For this reason mesotan should always be placed in a bottle which is absolutely dry and which is kept well corked when not in use. Again, this remedy should never be mixed with water, as this also tends to decompose it. Another important point which must be attended to is to see that the patient's skin is carefully dried with a towel before the mesotan is painted over it. Moreover, after its application the affected area should not be covered up by any impervious material which would allow the accumulation of sweat upon the surface of the skin. I think if these details are attended to mesotan will be found to be a useful remedial agent and one which does not, as a general rule, produce any untoward results. As an additional precaution, where this remedy has to be used for a lengthy period I always advise the applications to be discontinued at the end of a week and not renewed until after the lapse of two or three days.

I am confident that those of you who may not have had an opportunity of trying aspirin and mesotan will find that in these two agents we possess very potent remedies against rheumatism and rheumatic affections and that at the same time aspirin is of considerable value in certain other painful and febrile conditions.

Edinburgh.

A CASE OF HÆMATOMA OF THE OVARY SIMULATING AN ATTACK OF APPENDICITIS.

BY HAROLD W. WILSON, M.R.C.S. ENG., L.R.C.P. LOND.,
SENIOR HOUSE SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE patient, aged 19 years, an unmarried woman, was admitted into President ward, St. Bartholomew's Hospital, on Feb. 11th, 1905, under the care of Mr. H. J. Waring, complaining of abdominal pain and general malaise of two days' duration. She had been in her usual fair state of health up to Feb. 9th. In the afternoon of that day, while sitting at her work, she was seized with sudden colicky pain in the right iliac fossa which lasted for approximately ten minutes. Then the acuteness of the attack wore off and she was left with a dull aching and a feeling of soreness in the same region which remained until the date of her admission. This pain was severe and was made worse by direct pressure and by movement. She vomited once at the time of onset and once subsequently in the evening of the same day. She had been more constipated than usual during the preceding week; otherwise no further symptoms could be elicited. There were no history of any hæmorrhage or discharge from the vagina, no pain on micturition, and no pain in the left iliac fossa. She had never had a similar previous attack and had never suffered from "indigestion" or from a purulent vaginal discharge. The catamenia had been regular every 28 days and of average amount. There had been no pain. The last normal period occurred from Jan. 3rd to 6th and had since then been absent.

The patient was seen in the out-patient department and was immediately admitted. When examined in the ward she was lying comfortably in bed on her back with her right leg slightly drawn up. Her general condition was good. Although anæmic she did not look actually ill. The tongue was furred and showed no signs of cleaning. The pulse was 112, regular, and of fair volume and tension; it gradually dropped to 94 on the second day after admission. The temperature was 98·2° F. and remained subnormal throughout. Nothing abnormal was discovered in the thorax. The breasts were not active. The movement of the abdomen was fair but there was slight restriction in the lower part. No fulness was evident. There were considerable tenderness and muscular rigidity in the right iliac fossa, the most tender point being about two inches below the centre of a line drawn from the right anterior superior iliac spine to the umbilicus. No actual swelling was felt. On examination the vagina was found to admit two fingers, there being a very small crescentic hymen. No discharge was visible. The cervix was nulliparous, the canal being closed. There was considerable tenderness in the right lateral fornix. Bimanual examination was difficult owing to the patient holding herself extremely rigid. The uterus was normal in position and size. In the anterior part of the right posterior quadrant was a rounded, indefinite, elastic, tender swelling, which appeared to be about one and a half inches in diameter and was not continuous with the uterus. Per rectum there was tenderness in the region of Douglas's pouch but no actual swelling could be felt. The leucocyte count was 8000 per cubic millimetre and remained constant.

As regards the diagnosis, the patient was thought to be recovering from what was most probably a slight attack of appendicitis. Except for the continuous subnormal temperature the signs and the symptoms would do very well for the acute catarrhal form, occurring in a "south-east" appendix. But bearing in mind the missed period the possibility of an ectopic gestation was discussed, the symptoms fitting in with what would be expected in the case of an unruptured tubal pregnancy into the sac of which a small hæmorrhage had occurred. In these circumstances, after a couple of days' observation, it was decided to operate at once and not to risk any further delay. The abdomen was opened by an incision, rather lower than the usual appendicectomy one, the muscles being divided in the direction of their fibres. The appendix was found lying in the "south-east" position and appeared to be quite normal, except that at its tip it was attached to a swelling in the pelvis by a recent adhesion. In, and projecting from, the upper and back part of the right broad ligament was a globular purplish swelling about two inches in diameter. It was extremely tense and contained fluid. The tumour was identified as an enlarged right ovary over the apex of which ran the right tube with its fimbria ovarica attached to the swelling. A good pedicle was obtained, transfixed, and the tumour was removed; in so doing, however, the ovary ruptured and about one ounce of dark fluid blood escaped. The left ovary feeling normal the abdomen was closed. The patient made a good recovery.

The ruptured specimen on being hardened quickly contracted down to the shape and size of an ordinary ovary. Continuous sections showed the normal ovarian stroma to be infiltrated with blood and at one edge of the hæmatoma a mass of lutean tissue was seen. No trace of chorionic villi could be discovered.

During the last two years five somewhat similar cases of ovarian hæmorrhage coming on at or about the time of a menstrual period have been admitted into this hospital. In two of these [illegible] and there was a n[illegible] to a localised peri[illegible] more illustrating the extreme importance of carefully going into a woman's menstrual history in all cases of attacks of acute abdominal pain, even though the pain be not within [illegible] be, completely clears up in a week or ten days.

I am indebted to Mr. Waring for his kindness in allowing me to publish this case.

St. Bartholomew's Hospital, E.C.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF GENERAL SEPTIC PERITONITIS ON THE TENTH DAY OF ENTERIC FEVER WITHOUT EVIDENCE OF PERFORATION OF THE BOWEL.

By C. GORDON WATSON, F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE METROPOLITAN HOSPITAL.

THE patient, who was a boy, aged nine years, was admitted into the Metropolitan Hospital on Jan. 30th, 1905, with the following history. He began to suffer from headache and shivering on Jan. 21st but continued at school till Jan. 25th and then took to his bed. On Jan. 26th and 27th his principal symptoms were vomiting, delirium, and abdominal pain. On the 30th these symptoms increased in severity and the illness was certified to be enteric fever. The boy was thereupon removed to the North-Eastern Fever Hospital of the Metropolitan Asylums Board, from which he was at once sent to the Metropolitan Hospital with a provisional diagnosis of "appendicitis with peritonitis." I saw the patient immediately on admission. General peritonitis was evident. Laparotomy was decided on, though the case seemed hopeless. His condition before operation was as follows. The abdomen was uniformly distended, hard, and tender all over, scarcely moving on respiration, and dull on percussion in the lower half on both sides. The temperature was 102·6° F. and the pulse rate was 160. The tongue was brown and much furred, the patient was very restless, and *facies Hippocratica* was present. For the laparotomy an incision was made in the middle line below the umbilicus. The peritoneal cavity was found to be full of thin white odourless pus, with flakes of lymph on the intestines; there were no adhesions; the intestines were not much distended but were red and dull in places. Enlarged glands were felt in the mesentery and one which was pendulous at the root of the mesentery was removed for examination and proved to be tuberculous. The appendix was felt but was apparently not diseased. There was no free gas in the peritoneum nor was there any evidence of extravasation of intestinal contents. Two counter incisions were made, one in either flank, and the abdomen was rapidly irrigated with weak lysoform and finally with hot saline solution, some of which was left in. Three large drainage tubes were left in the incisions. The operation lasted 20 minutes. Restlessness and vomiting on the part of the patient continued and were temporarily relieved by a saline infusion but death occurred seven hours after operation.

At the necropsy much slightly blood-stained fluid was found in the abdomen; this fluid was quite odourless and there was no pus. The small intestines were slightly matted together by recent adhesions. The peritoneal surface was red and inflamed, especially near the ileo-cæcal valve. A careful search revealed no evidence of perforation and the bowel held water. When laid open the small intestine showed several early typhoid ulcers in the lower two feet and some swollen Peyer's patches. There were no sloughs. At one point the base of an ulcer seemed to be near the peritoneal coat, but the peritoneal coat was not visible from within at any point, nor was there any adherent spot which suggested a closed perforation. The large intestine was not involved. The spleen was very markedly enlarged. The glands in the mesentery were tuberculous but there was no evidence of recent activity or of rupture of any gland. Cultivations from the spleen and heart's blood gave pure cultures of the typhoid bacillus.

It may be remarked that peritonitis in enteric fever without evidence of perforation of the bowel is sufficiently rare to be worth recording, especially when occurring so early in the course of the disease. That no actual perforation had taken place in this case seems probable on account of (1) the absence of free gas or intestinal extravasation; (2) the nature of the pus (and the probable absence of bacillus coli); and (3) the condition of the ulcers and the peritoneal coat. It seems not unlikely that this was a case of pure typhoid peritonitis and had it been seen earlier might have been treated successfully. It is much to be regretted that no cultivations were made from the abdomen at the time of operation, but the case was very urgent and appliances were not at hand.

Welbeck street, W.

A CASE OF FÆCAL OBSTRUCTION DUE TO "TIGER-NUTS."

By EDWARD C. B. IBOTSON, M.B. LOND.

I WAS called on April 9th to see a boy, aged 12 years, who was said to be suffering from stoppage of the bowels. He was a stout, ruddy boy whose bowels were usually very regular but for two days there had been no action of them. He complained of pain in the abdomen and the "back passage." Various aperients, such as castor oil and senna, had been giv[illegible]curred. The abdomen [illegible]ion in all regions. [illegible]bering Hilton's maxim, "Never neglect to examine the rectum," I did so and found it to be distended and packed with a dry, hard, chaffy mass quite unlike fæces. A portion which was removed for examination proved to be light-coloured chippy scraps of nutshell and fibre, practically not agglutinated by any fæcal material whatever. I elicited from the patient that he had had "a ha'porth of tiger-nuts"—he added that they "were very sweet and you got a lot for your money." I should imagine that he had eaten half a pound at least, probably more. Several large glycerine enemata, followed by soap-and-water, were necessary to effect thorough evacuation of the rectum. In two days he was able to take part in a swimming race. The director of the Royal Gardens at Kew states that the "nuts" are the tubers of *Cyperus esculentus*, a common tropical sedge. A lady nurse of my acquaintance tells me that she has known of several cases of obstruction of the bowels in boys from eating these nuts too greedily.

ST. MARY'S HOSPITAL.

A CASE OF IMPACTION OF A PIN IN THE VERMIFORM APPENDIX; FORMATION OF AN ABSCESS IN THE LIVER AFTER A LONG INTERVAL; RUPTURE OF THE ABSCESS INTO THE LEFT PLEURAL SAC; DEATH.

(Under the care of Dr. SIDNEY PHILLIPS.)

THE patient was a girl, aged 15 years. She felt well until Nov. 16th, 1904, when she was attacked by cold shivers and headache. She went to bed at once and had some pains about the umbilicus during the night. There was no vomiting. She was ordered medicine and a liquid diet by a medical man on the next day. Some diarrhœa followed and on the 24th there was pain in the left hypochondrium. The patient got gradually worse and she came under the care of Dr. Sidney Phillips at St. Mary's Hospital on the 29th. Her only complaint was of shortness of breath, but her pallor was intense; the temperature was 101·8° F., the pulse was 128, and the respirations were 40 per minute. There was dulness on percussion over the lower two-thirds of the left back and as high up as the fourth rib in the left axilla there was almost complete absence of breath sounds below the sixth rib, and above this there was bronchial breathing. The temperature rose in the evening to 103°. It seemed probable that she had an empyema, but an exploring needle introduced into the sixth space on the next day withdrew only blood from an evidently pneumonic lung. On Dec. 2nd loud tubular breathing was audible over the whole of the dull area in the left back, confirming the diagnosis of pneumonia. On the 3rd there was a crisis of the pneumonia, the temperature falling to normal, the pulse to 118, and the respirations to 30 per minute. But on the same night the patient became suddenly collapsed, the pulse being almost uncountable and the skin breaking into profuse sweats; her heart became displaced to the right, and Dr. E. Ash, the house physician, aspirated the left side of the chest below the angle of the scapula, withdrawing 25 ounces of pus. This gave considerable relief. On the next day the patient was anæsthetised and Dr. Ash, under the direction of Dr. Phillips, opened up the intercostal space previously aspirated, giving exit to 40 ounces more pus. There was no cavity as in an ordinary empyema, the solid lung being felt and seen close up to the ribs and only a very short drainage-tube could be inserted. Pus, however, discharged very freely and except for a temporary rise the temperature was normal but the pulse-rate kept up at 140 and there were signs of a pus collection in the left chest which was not drained by our wound. Mr. V. W. Low therefore, at the request of Dr. Phillips, made an incision in the fifth space in the left axilla and let out about 20 ounces of thick flocculated pus; the finger in the wound showed that this empyema cavity was quite shut off from the cavity previously opened. A large drainage-tube was inserted and the patient had a good night. On the next morning loud amphoric breathing was audible below the left clavicle due apparently to the pneumothorax produced by the opening up of the pleural sac. This passed off by the 7th. On the 8th the patient became much more dyspnœic, both lungs became the seat of coarse bubbling râles, seeming to be swamped by bronchial secretion, and death soon occurred.

At the necropsy by Dr. J. F. H. Broadbent the two separate openings into the left thorax were seen—one opening into a loculated empyema sac, the other into the general pleural cavity. The left lung was coated with lymph and the liver was enlarged. In the left lobe of the liver was an abscess containing about four ounces of pus and this lobe of the liver having become adherent to the diaphragm the abscess had burst through the latter into the left pleural sac. The vermiform appendix was swollen, thickened, and distended with fluid. On laying it open a pin one and a quarter inches long was found in it lying with the head downwards. The pin was rusty and was surrounded with fæcal concretion which had evidently been moulded on it while it laid in the appendix. There was no sign of acute inflammation or of pus in or around the appendix nor any perforation. It subsequently was ascertained from the relatives that the patient had two years before had an attack of what was considered to be appendicitis.

Remarks by Dr. PHILLIPS.—The pin had certainly lain a long time in the appendix and was probably the cause of the inflammatory attack from which the patient had suffered two years previously. After lying there for some time an acute infective process seems to have arisen in connexion with the appendix, giving rise to a hepatic abscess which burst into the pleural cavity and led to the symptoms of collapse which were relieved by aspiration. The pneumonia and loculated empyema must have arisen before this; the latter, though suspected, was not detectable at first, its percussion dulness merging into that produced by the consolidated lung. The abscess of the liver was not suspected, nor do I think that it would have been possible to detect it in the inaccessible position in which it formed.

A very similar case is reported by Dr. J. F. Payne[1] where post mortem a pin was found in the vermiform appendix surrounded by fæcal concretion. No symptoms had occurred except pain on the right side followed by pyrexia, signs of pyæmia, and death in three or four weeks, the necropsy showing a large abscess and two or three small ones in the liver and a small one also in the left lung. As in my own case, there was no sign of suppuration in or around the appendix. Hepatic suppuration is a very rare result of appendix inflammation. Treves computes it at 0·5 per cent. of cases. When it does occur there is usually suppuration in or about the appendix and the liver is permeated by channels of pus—suppurative pylephlebitis. It is much more rare for localised abscess to form in the liver, as in Dr. Payne's and the present case. In neither of these cases was there any pus formation around the appendix and the liver abscess probably resulted, as Dr. Payne suggests, from embolic detachment of part of a clot produced by the presence of the pin.

PS.—Since the above was written a case of appendicitis has been recorded in THE LANCET of April 29th, 1905, p. 147.

DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL

A CASE OF ABDOMINO-PERINEAL EXCISION OF THE RECTUM.

(Under the care of Mr. R. W. MURRAY.)

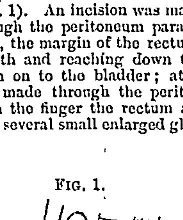
A MAN, aged 50 years, was admitted to the David Lewis Northern Hospital on Dec. 16th, 1904, on account of constipation and a feeling of discomfort in the rectum. For the past six months he had suffered from alternating attacks of diarrhœa and constipation and had noticed that the motions which he passed were becoming smaller and more elongated; relief was obtained with difficulty. He had occasionally passed slime but no blood. His general health had suffered and he was rapidly losing flesh. On admission he was a man of sallow complexion and looked older than his years. His chief complaint was a feeling of fulness in the rectum and an inability satisfactorily to empty the bowel. On examination a hard circular constriction of the rectum could be felt just within reach of the finger, but the upper limit of the growth could not be determined. The mass appeared to be freely moveable and as there was no evidence of secondary deposits elsewhere the case was considered a suitable one for operation. There was no abdominal distension or other evidence of marked fæcal accumulation.

---

[1] Transactions of the Pathological Society of London, vol. xxi., p. 231.

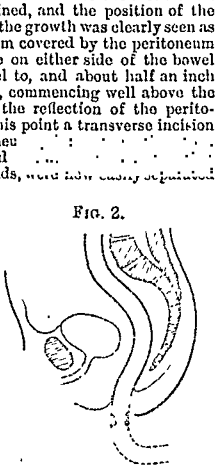
Operation.—On Dec. 20th the patient was anæsthetised and placed in the Trendelenburg position. The abdomen was opened in the middle line below the umbilicus by an incision five inches in length. An excellent view of the rectum and the pelvic colon was thus obtained, and the position of the portion of the bowel involved in the growth was clearly seen as it lay in the hollow of the sacrum covered by the peritoneum (Fig. 1). An incision was made on either side of the bowel through the peritoneum parallel to, and about half an inch from, the margin of the rectum, commencing well above the growth and reaching down to the reflection of the peritoneum on to the bladder; at this point a transverse incision was made through the peritone[illegible] With the finger the rectum and [illegible] with several small enlarged glands, were now easily separated from the hollow of the sacrum. The separation of the rectum was continued right down to the anus and the pelvic colon was freed until it was estimated that sufficient "slack" had thus been obtained to enable the bowel well above the growth to reach to the anal orifice easily. The abdominal wound was then completely closed. The patient was now placed in the lithotomy position and after widely dilating the anus a circular incision was made through the mucous membrane close to the anal margin, the mucous membrane was reflected for about an inch, and the rectum was then divided completely at this point. The rectum was pulled through the anus until the growth and healthy bowel above it were reached (Fig. 2). The protruding mass was then cut away well above the growth and the divided end was attached to the anal margin. A small gauze drain was inserted posteriorly between the cut edges.

FIG. 1.



Position of the growth.

FIG. 2.



Illustrating prolapsed bowel and growth.

The patient stood the operation well and made a very satisfactory recovery. For the first week following the operation he suffered from retention of urine and owing probably to the necessarily wide dilatation of the anus it was about three weeks before he had complete control over the anal sphincter. Offensive diarrhœa was another early complication, but this was found to be due to the accumulation of large hard masses of fæces in the rectum for the removal of which it was necessary to administer an anæsthetic. His general health and comfort have so greatly improved by the operation that he has been able to resume his former occupation of a millwright.

Remarks by MR. MURRAY.—Though it is no doubt true that in certain cases of carcinoma of the rectum when the growth is situated well within reach of the finger a good result may be obtained by the perineal or trans-sacral method of operating, still, if the truth could be known, it would almost certainly show that in the vast majority of cases the results obtained have not been satisfactory. The probable reasons for this are that in the first place this route does not permit of a clear view of the whole of the diseased area, and secondly, that only in exceptional cases can the divided end of the bowel above the growth be brought to the natural position of the anus. The abdomino-perineal method, on the other hand, with the patient in the Trendelenburg position, not only affords a good view of the diseased area and so enables the surgeon to see clearly what he is doing, but permits of the pelvic colon being freed so that the bowel well above the growth may be brought down to the level of the anus.

Sir Charles B. Ball in the Erasmus Wilson lectures on Adenoma and Adeno-Carcinoma of the Rectum, delivered in 1903, expressed himself as being by no means satisfied with the trans-sacral method, but concluded by speaking in most encouraging terms of the abdomino-perineal route, and in the same year an instructive paper appeared by by Dr. Louisa B. Aldrich-Blake,[1] in which a very clear account of the operation was given. Dr. Aldrich-Blake's operation differs in one important particular from that recommended by Sir Charles Ball. After opening the abdomen with the patient in the Trendelenburg position, and having freed the bowel well above and below the growth, Sir Charles Ball recommended division of the bowel *in situ*, after tying it above and, if possible, below the growth, in doing which there would certainly be a risk of soiling the peritoneum. Dr. Aldrich-Blake, on the other hand, after thoroughly freeing the bowel and growth, closes the abdominal wound and the growth is removed through the anus, thus avoiding all fear of peritoneal infection.

Though my experience of the abdomino-perineal operation has been limited to one case, I have been so favourably impressed with its advantages that I have ventured to give a brief account of the case in which I adopted it. The outstanding features of the operation are: (1) the extent of the disease can be clearly seen; (2) the whole of the diseased area can be freely removed, and this without soiling the peritoneum; (3) the anus is in the natural position; and (4) by denuding the small anal stump left of its mucous membrane, a procedure adopted by Moulonguet, a raw surface remains to which the prolapsed upper segment will attach itself, and at the same time the anal sphincter is retained.

In conclusion, I have to express my sense of indebtedness to Dr. Aldrich Blake, for it was entirely owing to her clear description of the operation that I obtained the success which I did.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

[illegible] ty *Growths.—Squamous-celled* [illegible] *Exposure to the X Rays.—New* [illegible] *olated from the Air.—Further* [illegible] *gy of Streptothrix Infection.*

A MEETING of this society was held on May 2nd in the Pathological Laboratory at the Middlesex Hospital, Sir JOHN BURDON SANDERSON, the President, being in the chair.

Dr. W. F. VICTOR BONNEY showed slides illustrating Nuclear Division in so-called "Gonorrhœal" Warts. Although the present investigation was by no means complete the slides that he showed exhibited a form of division apparently identical with the heterotype and homotype form of mitosis which was natural to gametic cells and which had recently been shown by Farmer, Moore, and Walker to occur freely in the cells of malignant new growths. He pointed out that if further investigation established this fact an explanation of the infective character of these neoplasms was at hand and would place them upon the same pathological footing as the intracystic papillomata occurring in certain ovarian cysts, in the epithelial cells of which the speaker had previously demonstrated the gametic type of mitosis at a previous meeting of the society. Although still called "gonorrhœal" these warts were well known to have no necessary connexion with gonorrhœal infection. Microscopically they presented the features of neoplasms and not inflammatory tumours, and he reminded the society that they occasionally exhibited a local infectivity and rapidity of growth that approached very closely to malignancy. It was therefore highly probable that the infective agent in these growths was the epithelial cell itself rather than a parasite and that this infective character was in some way closely associated with these abnormal nuclear changes. In view of the fact that gametoid mitosis occurred very freely in the locally infective ovarian intracystic papillomata and as now appeared in this form of infective wart also, he thought that these types of nuclear division must be held to be associated with the *infectivity* of a neoplasm rather than with the complex term *malignancy*.

---

[1] Brit. Med. Jour., Dec. 19th, 1903.

Mr. A. G. R. FOULERTON showed sections from a case of Squamous-Celled Carcinoma of the Finger associated with frequent and prolonged exposure to the x rays. The patient was a surgeon who had commenced systematic work with the rays in 1897. In May, 1903, a severe attack of dermatitis followed the performance of a long operation in the course of which the back of the left hand was closely exposed to the rays. Blistering of the skin of the back of the index and second fingers followed. The resulting ulcers healed after some four months, and the new skin was thin and tender and showed nævoid-looking petechiæ; the nails fell out and the new ones which formed were hard and brittle. A second attack of dermatitis, affecting especially the skin on the back of the index and second fingers of the left hand, followed another prolonged single exposure to the rays in December, 1903, and ulcers formed on each finger again. The ulcer on the back of the second finger healed but that on the index finger remained open and in April, 1904, began to assume a malignant character. Between May and September the ulcer slowly increased in superficial area and in depth and in the latter month the finger was amputated at the metacarpo-phalangeal joint. At the present time the skin of both hands was thin and of shiny appearance, numerous small nævoid-looking petechiæ were scattered over the dorsum of both the right and the left hand, and there was a small superficial ulcer over the middle phalanx of the second left finger. Otherwise the condition was quite satisfactory. Sections of the index finger showed a typical squamous celled carcinoma; cell-nest formation was frequent and conspicuous and the appearances generally were such as are usually associated with squamous-celled carcinoma of a chronic type. Mr. Foulerton did not think that the x rays exerted any special specific influence stimulating the activity of epithelial cells; all the evidence available suggested that the action was rather of an inhibitory nature At the same time this was the third case of the sort which had occurred amongst the comparatively small number of those who were working frequently with the x rays in London. The starting of malignant epithelial growth from the edge of a chronic ulcer was, of course, of comparatively common occurrence and the special liability of a chronic ulcer to assume a malignant character in these cases must be attributed to the general irritating effect of the x rays, the most obvious result of which was commonly seen in the dermatitis produced by exposure to their influence. In the present case it seemed probable that the ulcer having assumed a malignant character the growth of epithelium below the surface had been checked to some extent by the continued influence of the rays.

Mr. FOULERTON also showed Cultures of a New Species of Streptothrix, streptothrix Chalcea, which had been isolated from the air. Growth occurred freely on all the ordinary culture media and rather more freely at 37° C. than at 22° C. On nutrient agar the growth was of a copper colour, becoming a deep reddish-brown with age; gelatin was liquefied slowly; growth on potato was of a deep red colour, free, and of crystalline appearance; growth in broth produced typical round, flattened, streptothrix colonies; free growth occurred in milk, with the production of appearances often met with in the growth of members of this genus, the deposition of a very fine sediment from the milk and the gradual clearing of the medium. The thermic death point was between 60° and 70° C. The organism had a diastatic action on starch. The pathogenic action on lower animals had not yet been tested.

Mr. FOULERTON also read a paper entitled "A Further Contribution to the Pathology of Streptothrix Infections." Details were given of 33 cases which had been examined in the bacteriological department of the Middlesex Hospital during the last six years. Of these, six were probably cases of primary lung infection, there were four cases of appendicitis, and three cases of right iliac abscess in which connexion with disease of the appendix was probable but not proved, there was a single case of conjunctivitis, and there were 19 cases of lesions occurring about the mouth and neck in which it seemed probable that infection had occurred either through breach of the mucous membrane or through carious teeth. Of the 19 cases of mouth infection one was an abscess in the substance of the tongue, two cases represented an infection of the subcutaneous tissues of the neck, probably in one case following infection by the tonsil, there were two cases of abscess of the cheek, nine of the cases presented abscesses apparently connected with the mandible, and there were five cases of infection of the submaxillary region which might also have been connected with infection of the mandible. In nine of the cases no attempt to obtain cultures of the streptothrix was made but in all these a typical streptothrix parasite was seen in microscopic specimens. In the remaining 24 cases various culture media were inoculated in the hope of obtaining growth of the parasite present; in 12 of these cases the attempt either failed altogether or else the amount of growth obtained was so small that it was impossible to identify the species present. In the remaining 12 cases growth was obtained. The results were as follows: Streptothrix luteola (previously described) was obtained from the case of conjunctivitis and from one case of alveolar abscess of the mandible. Streptothrix hominis I. (also previously described) was obtained from two of the lung cases, from one case of infection of the subcutaneous tissue of the neck, from one abscess of the cheek, and from two abscesses connected with the mandible. Streptothrix hominis II., an organism of rather scanty growth, somewhat resembling *streptothrix hominis* I., was obtained from the case of abscess of the tongue. Streptothrix hominis III. was obtained from an interesting case in which the kidney was removed for suspected tuberculous disease. On examination of the kidney, however, the case proved to be one of streptothrix infection, the organism being demonstrated microscopically in the tissue of the kidney and recovered in culture. From a right iliac abscess an organism somewhat resembling the last but not sufficiently examined to determine its absolute identity was isolated. From another case, one of appendicitis, an organism, again closely resembling streptothrix hominis III. but differing from it in respect of its diastasic action on starch, was isolated. This case was one of considerable interest; the patient underwent an operation for appendicitis and shortly afterwards jaundice and severe symptoms supervened. The patient died and at the examination after death the appendix, which had been left, was found obstructed and thickened, the aortic and cœliac glands were enlarged and softened, and there was an abscess in the pancreas. The splenic vein came into close relation with this abscess and contained a purulent thrombus which had extended into the portal vein, which with its intra-hepatic branches was full of pus. Microscopic preparations of the pus from the pancreatic abscess and from the portal vein showed an immense quantity of the streptothrix, which was subsequently recovered in culture. In the series of cases examined the pathogenic action of the streptothrix had generally appeared to extend by continuity of tissue but, as in the last case, general infection was possible. Mr. Foulerton had not himself met with any of the cases, such as those recorded by Eppinger, Birt and Leishman, McDonald, Aoyama and Miyamoto, and others, in which widely spread infection had been associated with an acid-fast streptothrix. Owing to the kindness of Dr. McDonald he had, however, had the opportunity of examining the organism isolated from his case and he found that it corresponded in every respect with a culture which he had of Eppinger's streptothrix and caused a general infection in guinea-pigs.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 28th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Mr. J. JACKSON CLARKE exhibited three cases of Congenital Dislocation of the Hip reduced by the Method of Lorenz, with skiagrams. The first case was that of a girl, aged seven years, who had a typical displacement of the right hip, which was reduced in August, 1903. She was shown at the Clinical Society on Oct. 28th, 1904, with a skiagram, at which time the joint was stiff and abducted, exemplifying "the pubic position" with rigidity. Now the joint moved freely and without pain. The patient walked well and the restored joint was firm. The second case was that of a girl, aged eight years, who had been operated upon in August, 1903, for congenital dislocation of the right hip. This patient illustrated "the normal result"—*i.e.*, the walking and the anatomical conditions, save for a slight degree of abduction, which was purposely maintained, appeared to be the same as those of a normal child. The third case was that of a girl, aged three and three quarter years, who was operated upon for congenital dislocation of the right hip in June, 1904, with a good result —Mr T H OPENSHAW was of opinion that in one of the cases the head of the femur could be felt on the lip of the acetabulum He referred to the frequency with which the neck of the bone was rotated in this condition and the prognosis varied according to the degree of rotation After Lorenz s operation the head was never fully replaced in the acetabular cavity, but in spite of that the result was satisfactory inasmuch as the functions of the joint were restored —Mr JACKSON CLARKE agreed that often there was no true cavity into which the head could be placed, this could be well seen by dissecting the bodies of infants born with such a condition But the actual anatomical condition was unimportant so long as perfect movements resulted It was important to study the cases at some long interval after the operation

Dr H MORLEY FLETCHER and Mr H BETHAM ROBINSON exhibited a case of Dilatation of the Large Intestine beginning at the Hepatic Flexure and ending in the Rectum at the Pelvic Floor The patient, a boy, aged 12 years had always had a large abdomen In November 1904, there was a marked increase in abdominal distension, accompanied by constipation and some pain in defæcation Abdominal section disclosed the dilatation and the thickening of the large intestine The circumference of the upper part of the rectum measured 19¾ inches The bowel was emptied per anum by manipulation, many pounds of soft dark fæces being forced out The abdomen was then closed and the result had been very satisfactory —Dr J PORTER PARKINSON remarked on the distension of the veins upon the upper abdomen and discussed the possibility of some other morbid condition being present in the liver or the upper part of the abdomen —Mr DOUGLAS DREW referred to a similar case in a child about four years of age upon whom he had operated recently
he expressed the view that
the colon was in operation
the cases of this kind which he had seen the hypertrophy had been more limited in extent One case, that of a youth aged 19 years, came under notice for obstruction and died after colotomy and cæcotomy had been performed He advocated anastomosis of the sigmoid loop as the best surgical procedure —Mr ROBINSON remarked in reply that short-circuiting of the intestine in this case was out of the question because the hypertrophy existed as far as the anus

Dr J FAWCETT exhibited a case of Sclerodactylia with Vaso motor Phenomena A man, aged 21 years first noticed in May 1904 that his hands readily became cold and in September that his fingers became "thick and stiff so that there was difficulty in closing them His hands had now a permanently bluish white tint and were cold The feet and the lips were similarly affected The skin of the face and other parts was smooth, shiny, and tightly drawn When warmed the hands became very moist There was no ulceration Treatment by massage galvanism, thyroid extract, and nitroglycerine had been equally unsuccessful

Dr FAWCETT also exhibited a case of Xeroderma Pigmentosum (Kaposi s disease) A girl aged 16 year was first noticed to have freckles when aged two and a half years Until 14 she was at school and had no surface lesion For
s had appeared at
scars
Swelling of the Left
velling having
his before and

Dr A M GOSSAGE exhibited a case of Stokes Adams Disease The patient, a woman aged 58 years, went to the hospital a few weeks ago complaining of faintness, she had fallen several times and had had momentary loss of consciousness Her heart was beating regularly at 40 per minute, the heart and the pulse corresponding The pulse was strong and the arterial tension rather increased, with decided evidence of thickening and sclerosis of the vessel wall The heart itself was not enlarged and there was no marked hypertrophy to be made out and no murmurs were to be heard

Mr DOUGLAS DREW exhibited a case of Tuberculosis of the Parotid Salivary Gland The swelling had commenced in the patient, a boy aged nine years about eight months ago, simultaneously with a discharge from the left ear His father had died from consumption

Mr J R LUNN showed a case of Thoracic Aneurysm in the Right Carotid and Subclavian Arteries with weakness and blueness of the left hand and arm The patient, aged 35 years, was admitted with urethral stricture following gonorrhœa but without a history of syphilis Weakness and coldness of the left arm and abdominal pain had appeared five weeks ago A loud systolic murmur was to be heard over the aortic area the apex beat was in the sixth interspace below the nipple

Mr LUNN also showed a case of Tumour of the Tongue in a girl The patient aged 12 years first noticed a lump on the tongue six months ago About the middle of the dorsum of the tongue on the right side were two swellings one behind the other over which the papillæ were markedly hypertrophied On palpation the swellings were felt to consist of indurated tissue without nodules The right half of the tongue was larger than the left and the cervical glands on the right side were enlarged There were some scars at the left angle of the mouth and evidences of past keratitis —Mr W G SPENCER regarded the condition as one of lymphangioma with incipient macroglossia

Dr T D SAVILL showed a case of Traumatic Stricture of the Œsophagus possibly associated with Dilatation relieved by Electricity The patient a woman, aged 49 years in the year 1880 swallowed by mistake some vitriol This was followed by extreme dysphagia and stricture, so that two years later a small bougie could only be passed with difficulty After a time the difficulty in passing the bougie increased and when first seen in June 1903 a bougie had not been passed and she had not swallowed solids for nine weeks and fluids could only be swallowed with the greatest difficulty She had seen several surgeons and gastrostomy had been discussed Electric treatment was quickly followed by improvement, in six weeks she could swallow minced meat and had gained seven pounds in weight The improvement was maintained for 18 months when a relapse required a renewal of the electricity and she could now take solids without having to pass a bougie

Mr CHARTERS J SYMONDS exhibited a case of Ununited Fracture of the Tibia and Fibula in a man, aged 40 years to which a walking apparatus had been fitted and there had since been marked progress towards union —Mr OPENSHAW endorsed the efficacy of this apparatus in such cases

Mr CHARLES GIBBS exhibited a case of Multiple Circumscribed Fibrous Masses in the Corpora Cavernosa in a man, aged 48 years

Mr T CRISP ENGLISH exhibited a case of Traumatic Cephalhydrocele in a boy aged eight and a half years who when six months old fell 12 feet on to a stone floor and was unconscious for three hours

Mr SPENCER showed a case of Abnormality of the Left Testis The patient aged 21 years had never felt either in the left scrotum or groin a testis like the right one

Dr CHARLES BOLTON exhibited a case of Absence of the Abdominal Muscles in a male child, aged three weeks The recti abdominis were present but not the lateral muscles There were hypertrophy and dilatation of the bladder and undescended testes

---

LIVERPOOL MEDICAL INSTITUTION

Hydatid Cyst of the Lung —Second Dentition —Instruments for Recording Blood Pressure —Surgical Treatment of Chronic Constipation —Exhibition of Specimens

A MEETING of this society was held on April 27th, Dr JAMES BARR the President being in the chair

Dr A GORDON GULLAN read a note on a case of Hydatid Cyst of the Lung The patient a woman aged 38 year was admitted to hospital in June 1903 She was then very thin weighing only 7 stones and the right lung showed signs of consolidation from the fourth rib to its base and there was a large cavity in the upper part She expectorated
a to that of a
muco purulent
alin inhalations
and intra tracheal injections consisting of menthol 10 per cent guaiacol 2 per cent, and olive oil 88 per cent, from one to two drachms being injected daily No hydatids were expelled after July 20th and the patient made a satisfactory recovery, having since gained 2 stones 10 pounds in weight —Mr COLIN CAMPBELL said he had no experience of the treatment of hydatids of the lung but could hardly

believe that injections of such small quantities of oily solutions could produce much eliminative effect, they would simply float on the contents of the cavity. He had for years employed heavy glycerine solutions which by displacing muco-purulent secretions in pulmonary cavities brought antiseptic drugs into direct contact with the diseased tissues.

Dr. HUBERT ARMSTRONG read a note on the Second Dentition—its Medical Aspects. He dealt with the subject under the following headings: (1) general or local disease as a cause of faulty dentition; (2) faulty dentition as a cause of general or local disease; and (3) the influence of dentition upon concurrent general disease. Under the first heading reference was made to rickets, cretinism, syphilis, the exanthemata and other acute febrile diseases, adenoids, thumb-sucking, &c. The second section dealt with general symptoms, ulcerative stomatitis, anæmia, dyspepsia, and other symptoms and diseases associated with the second dentition; while in the third section the neuroses, epilepsy, chorea, and acute febrile illnesses were briefly mentioned. The importance of good health in insuring a sound dentition and *vice versâ* that of a sound dentition to the general health in after life were emphasised, and it was pointed out how in various ways the medical man could supplement the effort of the dental surgeon in this double object.

The PRESIDENT exhibited and explained the use of Several Instruments for Recording the Blood Pressure.

Dr. W. BLAIR BELL read a note on the Surgical Treatment of Chronic Constipation. He did not consider that ileo-sigmoidostomy was a suitable operation for dilated conditions of the big bowel owing to the "backing up" which occurred. He thought cæco-plication or excision of the dilated portion of the cæcum more rational. Ileo-sigmoidostomy, however, was valuable in those cases in which the big bowel was contracted and he related a case of this kind in which he had performed ileo-sigmoidostomy with satisfactory results. He was convinced that one operation, however, could never be successful in all cases of intractable constipation and that until the various pathological conditions obtaining in chronic constipation were accurately defined and rendered possible of recognition clinically surgical procedures could not be carried out on empirical lines.—Dr. W. ALEXANDER, Mr. F. T. PAUL, and Dr. R. E. HARCOURT took part in the discussion.

Mr. RUSHTON PARKER showed models of an old Roman Catheter, a Rectum Dilator, and an Unguent Injector. He also showed drawings, coloured photographs, and lantern slides of a few cases, some unusual, recently under observation. They comprised chancre of the mammary areola, sarcoma of the chest wall recurring after the excision of a cystic adenomyxoma of the breast, a galactocele containing inspissated milk, the brain and spinal cord from a case of cerebro-spinal meningitis, and a large prostate removed a week previously by suprapubic cystotomy.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Asylum Dysentery.—Poisoning by Carbon Monoxide.

A MEETING of this section was held on April 14th, Sir JOHN W. MOORE, the President, being in the chair.

Professor E. J. MCWEENEY showed a large series of Cultures of an Organism which he had isolated by the Drigalski plate method from the muco-purulent stools of a typical case of asylum dysentery. He also showed, for purposes of comparison, parallel cultures of genuine typhoid fever bacillus and of two strains of bacillus coli, one derived from human stools and highly pathogenic for rabbits, and the other freshly cultivated from a pure water-supply and presumably non-pathogenic. The organism of dysentery was thus shown to have the closest cultural resemblance to the organism of typhoid fever. the chief morphological difference being its non-motility. The chief cultural differences appeared on Endo's fuchsin medium and in mannite agar. Professor McWeeney discussed the question as to the identity of the organism isolated by him with that of Shiga and Kruse. For the material he was indebted to Dr. P. Heffernan, assistant medical officer at the Clonmel District Asylum.—Dr. A. R. PARSONS expressed the hope that Professor McWeeney would be able to keep a strain of this micro-organism growing, so that other cases of asylum dysentery might be tested against it.

Dr. W. J. THOMPSON described a case of Poisoning by Carbon Monoxide. The circumstances were unusual, in that the poisoning was due not to inhaling ordinary coal gas but to the patient being in a small room (17 feet by 8 feet by 7 feet) with a smouldering fire. It took place on one of the dredgers belonging to the Port and Docks Board. The patient was admitted to Jervis-street Hospital, Dublin, on Nov. 12th, 1904; he was in a state of deep coma and had a dusky, dark-greyish colour; the respirations were short, shallow, and stertorous, about 24 per minute: the pulse was small and thready; the first sound of the heart was lost; the pupils were irregular; the surface of the body was cold and the abdomen retracted; there was also suppression of urine. He was treated by hypodermic injections of digitalin, strychnine, and ether, by continued artificial respiration with inhalation of oxygen, by blood-letting, and by the application of heat to all parts of the body. The blood when drawn off had the characteristic bright red colour of carbon monoxide poisoning. The patient regained consciousness towards evening and left the hospital in 15 days perfectly well. On the first day he only passed nine ounces of urine, on the second 15 ounces, and on the third 23 ounces, and afterwards the normal quantity; no sugar or albumin was detected and the amount of urea per ounce was normal.—Professor MCWEENEY stated that he had made an examination of the blood from Dr. Thompson's patient. The first specimen he examined was too small in amount for detailed examination but presented all the appearances of the presence of carbon monoxide gas combined with the hæmoglobin. At a subsequent examination no trace of carbon monoxide gas was found and the leucocyte count was also normal.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on April 14th, Dr. J. F. J. Sykes, the President, being in the chair.—Mr. G. H. Fosbroke, county medical officer of health of Worcestershire, read a paper on the Midwives Act of 1902. The full provisions of the Act would not, he said, come into force until April, 1910, and meanwhile all respectable women already practising, if enrolled before April of the present year, would be entitled to call themselves midwives, though others might act as such if they did not assume the name. The central administrative body was the Central Midwives Board, consisting of five physicians, three ladies, and one layman; the local supervision was vested in the county or county borough councils which were empowered to delegate it to committees to which other persons and ladies might be coöpted, or, a course which he held to be open to grave objections, to the district councils. They were advised by the Central Board to appoint the county medical officer or where there was none some other selected practitioner, with or without assistance, as chief executive officer with disciplinary power. In his own county the committee comprised nine councillors and five coöpted ladies, while he had secured the assistance of a lady M.B., B.S. Lond., D.P.H. Cantab., the wife of a medical man. The need for some legislation was obvious when they considered that fully 60 per cent. of births were attended by midwives who were responsible for the majority of the 2000 deaths from puerperal fever yearly. As to the intelligence and character of these women, 11,475 of whom had been enrolled up to Dec. 31st, 1904, he might say that of 581 in his own county, every one of whom had been visited by him or his assistant, only 22, or 4 per cent., had a certificate of any kind. 11 per cent. were absolutely illiterate, 17 per cent. were over 65 years of age, 8 per cent. were very dirty, 16 per cent. had no washable dresses, 10 per cent. lived in filthy houses, and 5 per cent. were suspected of drink—that is, allowing for a plurality of faults, at least 50 per cent. were, properly speaking, unfit from causes other than professional ignorance. The Central Board had issued a number of rules and recommendations, excellent in themselves but some of them useless or dangerous in view of the class of women enrolled. Rule 1, Section E, required the midwife to be scrupulously clean in every way and to wear a clean washable apron over a washable dress, and not to go from a case with foul-smelling discharges to another without changing her dress and thoroughly cleansing and disinfecting her hands, arms, and instruments. He had known a very dirty midwife doing a large practice with suppurating ulcers on her legs which she dressed with a single layer of rag. Indeed,

the simple and obvious duties here enjoined had deterred not a few from enrolling Rule 2 Section E, specified the instruments the midwife should carry, viz scissors, nailbrush,
and vaginal syringe,
But of what use was
id, or, indeed, to many
who could, very few of such women could be safely entrusted with a catheter, and as to vaginal douches which were disapproved by the best authorities in normal cases they were already in the hands of the dirty and ignorant a frequent cause of puerperal fever A leathern bag into which the instruments would often be put without previous cleansing would be highly infective and he recommended Dr Barwise s suggestion of a white linen bag with pockets, and if desired, a waterproof cover, as very cheap and easily washed Next in importance to the precautions for the prevention of puerperal fever, in respect of which the majority of midwives were scandalously negligent, were the steps to be taken in the event of its occurrence Apart from its notification to the sanitary or district authority through which the local medical officer of health became cognisant, the midwife was required by Rule 18 Section 3, to notify the case within 12 hours to the local supervising authority, usually the county council Mr Fosbroke had recently heard, through the local medical officers, of ten cases occurring in the practice of midwives not one of which had been reported by them though four ended fatally The absence of any provision in the Midwives Act for the payment of medical men called in was a grave omission which might be met by a one clause Amendment Act, for the county councils had no legal power to pay while the guardians and sanitary authorities had no *locus standi* The registration of stillbirths called for strict investigation The disinfection of clothing and bedding save by boiling, was in a very unsatisfactory state a small minority only of the sanitary authorities possessed proper steam disinfectors, the "stoving' sufficient for killing vermin being quite inadequate The means for inquiring into the character of midwives as regards insobriety ignorance, negligence, or malpraxis were unsatisfactory and there were other defects and omissions in the Act which called for consideration —Dr O J Cullingworth speaking for the Central Board, said that the rules would be revised after three years' experience of its working but since there were 22 000 midwives already enrolled there was no fear of a dearth until the supply of qualified women was adequate The provision *re* stillbirths was intended to force the hands of the legislature in the interest of vital statistics —Dr J W Hembrough of Northumberland said that his council had received only 85 applicants, of whom 50 had been enrolled but 35 were more or less illiterate They did not insist on the instruments which few were competent to use They paid medical men for notifying puerperal fever but not for medical assistance His council was tr
Dr J R Kaye said that in
934 women, of whom 37 p
and very few had washable dresses Besides these 135 continued to practise largely under cover of medical men and many refused to be enrolled or gave up practising rather than comply with the rules Numbers of those who had registered did not know what a thermometer was or how to use a catheter and their syringes, &c , were put away dirty and blood stained The only disinfection on which he relied was by boiling for 35 minutes —Mr O E Paget said that in Northamptonshire 400 applicants had been reduced to 100 by retirements brought about by the visits and representations of an inspector a L O S , who gave instruction to the rest —Mr J Tubb Thomas said that in Wiltshire of 500 midwives in practice before the Act only 100 could enrol, the majority being illiterate he had had their thermometers marked with a red line at 100 4° —After Dr J S Tew Dr E O Seaton, and others as well as some ladies had spoken the secretary of the Central Midwives Board stated that the rules would be revised thoroughly next year He deprecated delegation which was resorted to where there was no county medical officer of health an omission in which Kent wealthy though it was set a bad example According to the census there were 30,055 midwives of whom 22 000 had enrolled though many of these seemed to desire the certificate as an ornament only and some claimed to have been in practice for 60 years The absence of any provision for payment of medical men was a defect on which they had asked the Privy Council and the Local Government Board to legislate The midwife s certificate ought to be equivalent to the order of the relieving officer A definition of an 'offence for which a midwife might be removed was wanted, one woman was convicted of keeping a lodging house for which a licence had been refused because she kept a brothel also and another who had a milk shop had been fined for adulteration But these defects were due to its having been a private Member s Bill rushed through in two and a half hours on a Wednesday afternoon

British Gynæcological Society —A meeting of this society was held on April 13th Dr William Alexander, the President being in the chair —Professor O Jacobs (Brussels) read a paper on Surgical Intervention in Cancer of the Uterus with actual results Surgical treatment of uterine cancer must have two essential objects total ablation of the infected organs and removal of the neighbouring lymphatic territory Surgeons were not unanimous as to the best form of treatment Intervention must take place as widely as possible from the seat of the infection and the sooner done the less the chance of extension The only chance of cure was early diagnosis and prompt intervention In 13 cases of supravaginal amputation 12 showed recurrence within one year and one 15 months later Vaginal hysterectomy was systematically performed in 81 cases with an immediate mortality of 1 2 per cent while in four years not one patient was alive Abdominal hysterectomy was performed in 95 cases with an immediate mortality of 6 3 per cent and recurrence took place within six years in the remainder In both varieties of cancer of the cervix infection took place through the lymphatics consequently all glands of parametrium and cellular tissue must be removed Glands were invaded beyond the limits visible to the naked eye The invasion of tissues and glands was demonstrated far from the primary growth Cancer did not recur but continued and would not reappear if completely removed Actual results appeared to prove either that cure was usually impossible or that operations were imperfect Cancer of the cervix being primarily a local infection propagated by lymphatics induced Professor Jacobs to advocate abdominal hysterectomy Reports on five inoperable cases were given which improved sufficiently to permit of intervention after injections of Doyen s anti neoplasic serum —Professor J W Taylor considered it had been well shown that cancerous deposit was found at a considerable distance from the point of invasion He was interested in the reference to the serum treatment and agreed with Professor Jacobs that it was not possible to judge of results at present —Mr F Bowreman Jessett gave a series of 160 cases removed by the vaginal method with the exception of two or three by combined operation He preferred the vaginal operation If the sacral or lumbar glands were involved it made little difference which method was adopted —Miss L Garrett Anderson was interested to know that Professor Jacobs approved of the abdominal rather than the vaginal route —Dr George Elder considered that the low rate of mortality *must be attributed to the operative dexterity* of Professor Jacobs —Dr Thomas Wilson considered that the results of extensive abdominal operations were certainly no better than those by the vaginal method —Dr F J McCann opposed the extensive operations now practised in carcinoma of the uterus owing to anatomical difficulties of removal The supravaginal method had still a place in treatment In the vaginal operation he removed considerable portions of the anterior and posterior walls of the vagina with the cervix —Dr T A Helme considered

that the abdominal route was to be preferred but while operative results remained as at present many would choose the vaginal method —Mr Christopher Martin wished for fuller details as to Professor Jacobs s method of performing abdominal hysterectomy —Miss L B Aldrich Blake had practised the abdominal method for the last four years in cancer of the cervix She had 15 cases with no operative
final result
Macnaughton
the certainty of lymphatic invasion the difficulty of reaching the limits of that infection and that a period of five or six years must elapse before any case could be considered cured He had to make 700 sections of a lymph gland before finding evidence of carcinoma in one of his cases —Professor Jacobs, in reply, said his paper was limited to cancer of the

cervix and his results after vaginal hysterectomy were discouraging. The results of abdominal hysterectomy with clearing out of pelvic tissue were unsatisfactory but by improving his method he hoped for still lower mortality results. Finally, he urged the abandonment of vaginal in favour of abdominal hysterectomy in cancer of the cervix.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at 20, Hanover-square, London, W., on April 19th, Mr. William Bowen Davies (Llandrindod Wells), the President, being in the chair.—Dr. Henry McClure read a paper on the Climatology of the Sahara. He spoke of the several characteristics of the desert; of his experiences of the great desert regions of North America lying between the Rocky Mountains of Colorado as well as of the Sierra Nevada of California; and of the points that differentiated the climate of the desert from that of other regions. Climatic features in the Sahara were the absence of clouds, the peculiar properties of the desert air, the wide range of temperature, and the absence of moisture which enabled people to endure such extremes without discomfort. Biskra with the Sahara country about it and the mirage were described. The climate indications in diseases of faulty metabolism or those due to toxins and neuritis were touched upon. The striking psychical influence of the desert environment was strongly emphasised.—Dr. E. Symes-Thompson compared, from personal observation, the climate of Biskra with that of Helouan and Assouan. He said that desert air, by promoting evaporation, metabolism, and elimination, was of proved value in many rheumatic and gouty affections, and especially in syphilis and in renal disease. The desert between Khartoum and Fashoda was becoming more and more accessible as a health resort.—Dr. C. Theodore Williams said that the climate of the desert was characterised by great insolation, extremes of temperature, marked radiation, and wonderful dryness, and the result was a most exhilarating influence on the nervous system and marked stimulation of the processes of secretion and metabolism. He recommended the desert climate for patients suffering from chronic rheumatism, chronic bronchitis, asthma, and limited tuberculous cavity in the lungs. He wished the climate of the Egyptian desert could be rendered available for patients of moderate means.—Mr. W. Armstrong (Buxton) said that while practising in Egypt during the past winter he had observed patients at Mena, on the edge of the desert, at Helouan, in the desert, and also in desert camps. Cases of rheumatism, rheumatoid arthritis, neuritis, and atonic gout were greatly benefited. He considered that there was a great future before treatment in small camps. At present the expense and the loneliness were objections but by next winter arrangements would be made for combined camps, by means of which expense would be much reduced and some companionship assured.—Dr. J. T. Leon (Southsea) stated that he had quite recently been in Biskra and had experienced the exhilarating effect of the desert air. The water was extremely hard, in fact, brackish, owing to the large amount of sodium chloride and lime salts. This, combined with the keen air, played havoc with ladies' complexions and made toilet operations unpleasant. The life was distinctly monotonous and after a time rather depressing.—Dr. Leonard Ll. B. Williams, Dr. Harry Campbell, Dr. R. W. Felkin, and Dr. P. G. Lewis (Folkestone) also took part in the discussion.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 13th, Mr. W. Horton Date, Vice-President, being in the chair.—Mr. G. L. Thornton read a paper on Modern Therapeutics. He began by calling attention to the modern tendency to the unnecessary prescription of the compressed drug which had the disadvantage of encouraging self-medication by laymen. He then passed in review various lines of treatment, firstly, remedies which we owe to bacteriology. The great reduction in the diphtheria mortality due to antitoxin was emphasised. He commented on the larger dosage of the antitoxin in vogue now in comparison with the number of units employed some five years ago and, drawing from his own statistics, questioned if this larger dosage was always necessary. In tetanus it was a question whether recoveries were *post hoc* or *propter hoc* with respect to serum treatment. He mentioned the striking results from the use of Sclavo's serum in anthrax but was sceptical of the value of antistreptococcic serum, which needed further elaboration. The open-air treatment at present held out best hope of cure in pulmonary tuberculosis, althou[illegible] future an antitoxin would probably be found, when a combination of these methods was not unlikely. He touched on protection from typhoid fever and referred to the valuable lecture by Dr. F. F. Caiger[1] on treatment in this disease. He drew attention to the dangers of tar derivatives in influenza and advocated a more general employment of quinine. He recommended that measles should be made generally notifiable. In whooping-cough he mentioned the good results which he had obtained with quinine. He discussed the displacement of sodium salicylate by aspirin in acute rheumatism and considered that failure with sodium salicylate was often due to the employment of an impure preparation. In spasmodic asthma patients sometimes triumphantly referred a cure to the use of a proprietary remedy administered in an atomiser and he commented on the position of medical men in the matter from the point of view both of humanity and professional ethics. In the treatment of broken-down compensation in heart disease Dr. A. Morison had compared the physician to the surgeon in the presence of a grave catastrophe and had advocated the administration of digitalis in maximal pharmacopœial doses—and even higher if necessary—at frequent intervals. Mr. Thornton criticised the modern tendency to run riot in organotherapy and mentioned as the latest example the employment of extract of raw kidney in Bright's disease; in the latter disease he testified to the value of small doses of morphine for uræmic symptoms. In diabetes the dietetic treatment was less rigid and he mentioned the value of potatoes as a means of supplying carbohydrates. The yelk of egg had been found useful as a vehicle for fat easy of assimilation.—In the discussion which followed Mr. Date, Dr. J. A. W. Pereira, Dr. R. V. Solly, and Dr. C. J. Vlieland took part and Mr. Thornton replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 14th.—The following cases, pathological specimens, &c., were shown:—Mr. J. F. Dobson: A case of Bilateral Congenital Dislocation of the Hip in a patient 10 years old.—Dr. J. C. Teasdale: Anencephalic Fœtus with Extroversion of Abdominal Viscera.—Dr. T. Churton: Bilateral Empyema in a child, aged two years; one side was incised and the other was aspirated.—Mr. H. Littlewood: (*a*) A case of Proctectomy; (*b*) Ectopic Gestation; (*c*) Parovarian Cyst with a Twisted Pedicle; (*d*) Calculus in the Vermiform Appendix; and (*e*) Osteoma of the Upper Jaw.—Dr. T. Wardrop Griffith: (*a*) Imperforate Anus with Atresia of Duodenum and other formations; and (*b*) (with Mr. Nixon) Complete Pulmc Atresia in a man, aged 35 years.—Dr. W. H. Maxwell Tel (*a*) Aortic Stenosis in a boy, aged 17 years; (*b*) A Stenosis in a girl, aged 13 years; (*c*) Chronic Urti with Pigmentation in a child; (*d*) Tuberculoma of the Thalamus and Corpora Quadrigemina from a child agec years; and (*e*) Deformed Liver showing Constrictive L —Dr. J. B. Hellier: (*a*) Tuberculous Salpingitis; (*b*) My Uteri; and (*c*) Fibro-cystic Myoma.—Dr. E. F. Trevel (*a*) A case of Tabo-paralysis; (*b*) an early case of Ge Paralysis; (*c*) a specimen of Multiple Tuberculous M in the Brain; and (*d*) a specimen of Secondary Carcin the Pons.—Mr. E. Ward: Hypernephroma (suprarenal tumour of the kidney).—Mr. A. L. Whitehead: Parts rem from a case of Submucous Resection of the Nasal Septun Complete Obstruction of the Nostril. The patient was shown.

ROYAL DEVON AND EXETER HOSPITAL.—A months ago Mrs. Nosworthy of Dawlish gave the of £1000 for the purpose of erecting a new operating the for the Royal Devon and Exeter Hospital. It has since been discovered that the cost of the undertaking will £1500 and when Mrs. Nosworthy was acquainted with fact she generously decided to give an additional £50 complete the work.

PHYSICAL AND MENTAL DEGENERATION.—T will be a meeting in the I[illegible] go[illegible] a case day next, May [illegible]ner without changing delivered by [illegible]leansing and disinfecting her Causes a[illegible]nts. He had known a very dirty posed [illegible] practice with suppurating ulcers on [illegible]essed with a single layer of rag. Indeed,

[1] THE LANCET, Nov. 26th, 1904, p. 1467.

Reviews and Notices of Books.

A Treatise on Plague, dealing with the Historical, Epidemiological, Clinical, Therapeutic, and Preventive Aspects of the Disease By W J R SIMPSON, M D Aberd, F R C P Lond, D P H Cantab, Professor of Hygiene, King's College London, Lecturer on Tropical Hygiene, London School of Tropical Medicine, formerly Health Officer, Calcutta, &c Illustrated by Maps, Diagrams, Charts, and reproductions of Photographs Cambridge The University Press 1905 Pp 466 Price 16s net

Professor Simpson by his wide experience of plague in many countries and in all its bearings and by his personal and scientific attainments is eminently fitted to deal with a subject which he has made peculiarly his own, and he has evidently spared no pains to render his work authoritative, comprehensive, and practical Naturally the greatest amount of interest is centred in India, for plague has in India attained so firm a hold that we doubt whether any records of ancient or mediæval times surpass the enormity of the scourge now prevailing in that country

The subject of plague is divided into four principal parts The three chapters of Part I are devoted to the History and Distribution of Plague. Chapter I deals with Plague from the Early Centuries to the Nineteenth Century Under this heading is given a succinct and interesting account of plague from Biblical to modern times Commencing with the first well authenticated pandemic which originated at Pelusium in Egypt in 542 B C and its subsequent extension to Constantinople described by Procopius of Cæsarea we are afforded a historical picture of the way in which plague maintained its prevalence throughout the sixth, seventh, eighth, eleventh fourteenth fifteenth, sixteenth, seventeenth, and nineteenth centuries down to the present day

Chapter II deals with Plague in India and Chapter III with the Present Pandemic The information afforded in the historical part of the work is comprehensive, lucid, and accurate In the statistical details of the plague in London evidence is again brought home to us of the persistency of plague when once it has attained a serious hold upon a locality or city For no less than 136 years—from 1543 to 1680 A D —did plague continue to threaten London, appearing during no fewer than 84 years of that period, and from 1605 to 1680, with the exception of four years deaths from the disease were recorded The inference to be drawn from the experience of London does not afford a hopeful prospect that the disease will be quickly eradicated from India as many anticipated when plague first appeared in Bombay in 1896 This part of the treatise is abundantly illustrated by clear and useful maps indicating the course and the prevalence of plague throughout the world

Part II is concerned with the Epidemiology of Plague The earlier views of the theory of contagion, the culture, the characteristics, the vitality and the varying virulence of the bacillus, are amply considered in Chapter IV, under the title of the ' Nature of Infection ' One of the most interesting chapters is that devoted to the Relationship of Epizootics to Plague It is curious to note how in even ancient times this relationship was observed and how disease and death in rats and mice have been always associated with plague in man Attention is also drawn to the results of Dr William Hunter's observations in Hong Kong showing "that the plague in rats continues to exist at a low level throughout the non epidemic period of plague" and that "the epizootic rises at the season when young rats are most numerous" Inquiries made among European medical men in South China by the author afforded practically unanimous evidence that the rat mortality is a precursor of plague A careful analysis of the experiments made by the German and Austrian commission, by Professor Simpson and Dr Hunter in Hong-Kong, by Mr Ernest Hill in Natal, and by other observers tends to show an intimate relationship between plague-infected animals and the disease in man, and the chronicity of the infection of some animals is important evidence as to how a prolonged continuation of plague may prevail in endemic centres

In Chapter VI we are made acquainted with the "different views as regards the etiology of pandemics and epidemics of plague" Under this heading perhaps the most interesting facts will be found to be the abnormality of seasons and the exceptional meteorological conditions which have been noticed to precede epidemics of plague in many localities That these stand to each other as cause and effect may be questioned, for such varying influences as war, famine, wet seasons, drought volcanic eruptions, unhygienic surroundings, and political, social, or economical conditions the reverse of prosperous have all found supporters as etiological factors in bringing about an outbreak of the disease Epidemics of plague and seasonal influences afford a wide and useful field of study The most recent observations on this point are those of Gotschlich, quoted by the author who attempts to explain the regularity of the seasonal periodicity of plague in an infected locality by the seasonal breeding period of the rat and states "that in the plague free months many of the older rats suffered from a latent or chronic form of plague, while when the younger rats came into existence these young rats were susceptible to the acute disease" In Chapters VII to XI inclusive the subjects treated are the Variation in Powers of Diffusion of Epidemics, the Variation in Virulence of Plague Epidemics, the Fostering Conditions of Endemicity and Epidemicity, and the Diffusion and Modes of Dissemination of Plague

Part III deals with Plague in the Individual and in Chapters XII to XVI an excellent *résumé* of the morbid anatomy and the pathology, the clinical features (with reproductions of photographs of patients with buboes), the diagnosis the prognosis, and the treatment of the disease are concisely and clearly given

Part IV of the treatise is devoted to Measures for Prevention and Suppression of Plague This important subject is divided into five chapters and extends to no less than 80 pages The prophylactic measures employed before and after the discovery of the bacillus pestis are admirably enunciated and in no part of his work has the author shown more forcibly his qualifications for undertaking a book on plague We are especially interested in his recommendations as to the main lines along which inquiry in regard to plague is needed The more urgent questions to be answered by future investigators are some 17 in number, of which the chief are 1 The length of time during which an infected patient or infected animal retains infection 2 Whether rats or human beings are the chief disseminators of plague and in what proportion 3 Whether other animals are disseminators of plague without being affected themselves and in what way 4 Whether insects, such as fleas, bugs, flies, and so on, disseminate plague 5 What are the species of fleas on the rats, fowls, cats, and dogs in the locality investigated and which of them attack man? 6 Whether there are other modes of dissemination besides animals and insects 7 How is the infection conveyed from man to man and from animal to animal? 8 Does season affect the bacillus or its carriers? 9 What is the reason of dormancy in non epidemic seasons and what are the agents at work producing recrudescence? 10 What are the best *agents for destroying* the bacillus or its carriers?

These are but examples of some [illegible] problems concerning plague that await to be [illegible] the disease

"The Roman and the Teuton." All who are interested in he early history of our island should read Dr. Williamson's book, *for it tells the story of one who went out with his life* n his hand to conquer with no earthly sword and whose example no doubt inspired Livingstone, Patteson, and many others who have spent their lives in the service of their ellows.

Preaching and Healing, 1904. London: The Church Missionary House.—Under the above title the Medical Auxiliary of the Church Missionary Society publishes its annual report. It contains much information regarding medical missions in the East and the two maps which accompany the report, one showing the Mahomedan lands of the East and India and the other China and Japan, enable the reader to realise clearly the great extent of the operations of the auxiliary. The reports of the medical officers n charge of the various stations show that continuous progress is being made but it must not be forgotten that the work of the auxiliary entails a great strain upon its financial resources. Lack of monetary aid is not, however, the only difficulty with which the medical missionary has to contend. Mr. Leonard G. Hill, writing from Pakhoi, describes the case of a pirate who, after being treated for a bullet wound of the leg, stole money from his fellow patients and as soon as he could use his leg again left the hospital with a blanket. On the other hand, it is not an uncommon thing to meet with cases of genuine gratitude on the part of the patients. Pakhoi seems to be a very interesting station to the medical man. The officer in charge of this station reports: "We get an immense variety of diseases ...... but never enteric fever, scarlet fever, nor diphtheria. On the other hand, we get every skin disease there is and every eye disease known from a professional point of view, many affording the greatest clinical interest. Our clinic would be the envy of many a professional man in Europe, and indeed it would make a splendid training-ground for a medical career." Many other paragraphs might be quoted if space permitted, for the whole report is full of graphically written details showing the work that is done, and still remains to be done, in the mission field, he life which the self-sacrificing missionaries lead, the need for more labourers, and the help which those at home can render by more liberal financial assistance.

German Technical Words and Phrases: an English-German and German-English Dictionary. By C. A. THIMM, F.R.G.S., and W. VON KNOBLAUCH. London: E. Marlborough and Co. 1904. Pp. 218. Price 2*s.* 6*d.*; leather, gilt edges, 3*s.* 6*d.*—This is a companion to the little book of "French Technical Words and Phrases" which we believe appeared about five years ago. It is of a handy size for the pocket and contains a lot of useful information. Roman type, which is much preferred by many persons studying German, has been employed in place of he German characters throughout the volume. This little book is well worth possessing by those whose work brings them into frequent contact with German technical words in common use. The publishers now have the Italian volume in hand.

JOURNALS AND MAGAZINES.

The Practitioner.—The number of this periodical for April is distinguished by the variety of subjects considered in the articles that compose this issue of the journal. Dr. G. Newton Pitt, in an article upon Some Obscure Cases of Cancer of the Stomach, draws attention again to the diagnostic importance which he attaches to enlargement of the glands behind the eft sterno-mastoid muscle. The most important gland, he states, and often the only one to be involved, lies behind the two lower roots of the sterno-mastoid. In order to feel it it is often necessary to make the patient cough. This may be the only external gland affected by cancer within the abdominal cavity. Specific remedies for tuberculosis, the treatment of ringworm, the pathology of puerperal eclampsia, and the cyto-diagnosis of pleural and cerebro-spinal fluids are amongst the other matters discussed in a very interesting number of the magazine.

New Inventions.

THE "REED" HUMANISER.

THIS is an apparatus designed for modifying cows' milk so that the product shall conform as nearly as possible to the composition of human milk. The method is based on the principle that by allowing cows' milk to stand a portion of the skim milk may be run off by which the excess of proteid and salts is removed. Afterwards some milk sugar and a little water are added to the fatty portion. The apparatus employed for the purpose is simple enough and consists of a graduated jar provided with a draw-off stopcock and mounted on a stand. An ingenious balance accompanies the apparatus for measuring the requisite quantities of water and milk sugar but this has recently been superseded by the more convenient plan of tablets of milk sugar each containing a definite weight of sugar. The *modus operandi* is as follows. A convenient quantity of good fresh cow's milk is poured into the graduated glass vessel and allowed to stand until the cream has risen. The number of divisions of cream is noted. A definite proportion, according to the age of the infant or special requirements, of the separated milk is then drawn off. A definite quantity of water together with a specific number of sugar of milk tablets is then added to the remainder. The quantities required are indicated in the table provided with the apparatus. Proceeding in this way and following the directions given for a child aged six months we obtained from cow's milk a milk of the following composition: fat, 3·00 per cent.; milk sugar, 7·00 per cent.; proteid, 1·00 per cent.; and mineral salts, 0·37 per cent., which accords very well with the published analyses of human milk. The advantages of the method are simplicity, accuracy, and the use of a fresh and not a sterilised product. We have received also a statement as to the satisfactory results yielded by this method in actual practice. The apparatus is supplied by Messrs. Teed and Co. of 11, Grove Hill-road, Camberwell, S.E.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—The following is the pass list of the examinations held in April:—Of six candidates who entered for the intermediate examination three passed: J. D. Kettle, B.Sc. Lond., Elison A. Macadam, and R. Simmons. In the final examination for the Associateship (A.I.C.), of seven examined in the branch of mineral chemistry, three passed: J. Alexander, B. O'Shaughnessy, Assoc.R.C.Sc. Lond., and E. Rhodes, B.Sc. Vict.; of five in organic chemistry three passed: S. J. M. Auld, Ph.D. Würzburg, H. W. Goodwin, and R. Robison; and of eight who entered in the branch of the analysis of food and drugs and of water, including an examination in therapeutics, pharmacology, and microscopy, the following six passed: J. H. Barnes, B.Sc. Birm., J. W. Brisbane, D. Gair, B.Sc. Lond., H. G. Harrison, B.A. Cantab., R. Park, and J. Race. One candidate passed an examination for the Fellowship (F.I.C.): A. E. Brown, B.Sc. Lond. The examiners in chemistry were Mr. W. W. Fisher, M.A. Oxon., F.I.C., and Dr. G. G. Henderson, M.A., F.I.C. The examination in therapeutics, pharmacology, and microscopy was conducted by Dr. F. Gowland Hopkins, M.A., F.I.C.

THE LANCET.

LONDON: SATURDAY, MAY 6, 1905.

Underfed Children.

THE Order concerning underfed children which has been recently issued by the Local Government Board and explained and enforced by a circular letter from the Board of Education, is one which will be regarded from very different points of view by different persons. It imposes upon the managers of elementary schools the duty of discovering and of reporting to boards of guardians all instances of underfeeding among the children and it imposes upon boards of guardians the duty of seeing that necessary food is supplied, either as ordinary relief or as a "loan" to the father which may be recovered from him, if necessary, by county court process. It empowers the county court judge to make an order upon the employer of the father, under which the necessary portion of any wages due to the latter must be withheld from him and handed over to a court official. These somewhat drastic proceedings will, of course, be cordially welcomed by many who might be described primarily as educationists and who believe, as the matter has before now been stated, that the effects of schooling bear some analogy to those of a laminaria tent and that the introduction of compressed facts will suffice to bring about the mechanical expansion of the budding intellect. To such people schooling is the primary necessity of modern life, the one agency to which they look with hopefulness for the maintenance or the improvement of our position among the nations, the chief means for enabling us and our children to speak forcibly to the enemy in the gate. The Order will be equally welcome to the philanthropists who are prone to overlook the existence of two sides to every question and whose hearts have been wrung by piteous descriptions of the sufferings of vast numbers of half-starved children, whose parents, it is alleged, habitually spend in drink or in tobacco the money which should be used to procure food for their offspring. By the public generally it will probably be regarded as a well-intentioned and therefore praiseworthy endeavour to deal with an admitted evil but surely as an endeavour the character of which can hardly be correctly estimated except under the guidance of experience. There will at least be universal agreement with the view expressed by the Board of Education to the effect that the cost of obviating the consequences of parental neglect, when the existence of this is well established, should not be suffered to fall upon the ratepayers.

The whole principle of the Education Acts must be taken to rest upon the assumption that the children of the nation are, at least to some extent, the property of the nation and not the exclusive property of their parents. It rests, furthermore, upon the assumption that to suffer these children to grow up in ignorance will diminish their prospective usefulness to the State and that the State on this ground has a right to send them to school. If these propositions be admitted it certainly follows that the State has at least an equal right to concern itself with the prevention of any other unfavourable conditions by which eventual usefulness would probably be diminished; and this description would include not only underfeeding but also residence in unwholesome houses and, generally speaking, exposure to insanitary or demoralising conditions of any kind. Every argument which can be urged in support of the position that the State is called upon to intervene in order to cause children to be sufficiently fed can be urged with equal force in support of the position that it is called upon to intervene in order to protect them against small-pox and its sequelæ by compulsory vaccination, or against tuberculosis by the reform of slum dwellings, or against an inheritance of syphilis or of imbecility as a consequence of a marriage which due consideration of its probable consequences would have prohibited. The assumption of State property in the young, and consequently of State responsibility for their welfare, is manifestly one which may entail operations of indefinite magnitude and extent, only the smallest beginnings of which are as yet coming prominently before the public view; and the principle that it is the business of the State to remedy the neglects of parents, and to compel the parents themselves to defray the cost of the necessary proceedings, is one of which the full reach and the ultimate applications may at present be impossible to foresee. It is by no means to be accepted with a light heart or without much consideration alike of the consequences to which it may lead and of the methods which may be found necessary in order to reduce it to practice. All that seems at present to be decided is that every child in an elementary school who seems to the teachers or the managers to be underfed wil be supplied with food at the primary cost of the ratepayers and with some uncertain prospect of eventual recovery of the expenditure from the father.

It is only too well known to all who are concerned in the practical work of education that what may properly be called underfeeding is lamentably common and that children are constantly sent to school without having had any proper breakfast or without having any reasonable prospect of a proper dinner. The evidence rests partly upon their weakly condition, partly upon their answers to the questions that are put to them. As long as these answers can have no worse effect than to produce a probability of charitable feeding they are likely, within limits, to be true and trustworthy, but as soon as they become convertible into evidence against parents they are almost certain to assume a different character. Not only will the children be in fear of domestic consequences if they speak the truth but they will also be actuated in many instances by a desire to screen their parents prompted by the habitual attitude of their class towards persons in authority or towards the law. The teacher may suspect underfeeding and may fail to obtain any confirmation of the suspicion from the pupil. In such circumstances, we presume, the question would frequently be submitted to medical examination and [illegible] medical practitioner would be officially welfare we are nationally responsible and for whose possession and maintenance some of the noblest British blood has been shed. Now and again a frank correspondent, like our own, or a question in the House of Commons will give a picture of the actual condition of affairs, and one of the questions recently asked in the House of Commons elicited a statement from the Secretary of State for India that over 200,000 persons had died from plague in India during January and February of this year. To this statement was added the information that a committee would sit in London to consider the scientific aspects of the question and that two bacteriologists would go out to India to study the disease. We have commented in THE LANCET upon the inquiry undertaken jointly by the Lister Institute of Preventive Medicine, the India Office, and the Royal Society, the first-fruit of which is to be the despatch of two bacteriologists to the East, and while allowing that the idea of the inquiry is a sound one we have pointed out that we do not think the measures to be undertaken really meet the case. Three and a half millions of people have died from plague in India since 1896, and the proposal to send out two bacteriologists to look into the causes of the tragedy strikes us as inadequate, however capable and distinguished the gentlemen connected with the joint inquiry may be, and indeed are. The surplus of the Imperial Indian exchequer this year is £4,000,000 sterling. Some part of this surplus might well be used to set in motion machinery having for its object seriously to combat plague, so that something more practical, larger in design and more likely to lead to real and early preventive measures, might be undertaken.

Annotations.

"Ne quid nimis."

THE INDUSTRIAL CLASSES AND THE TREATMENT OF TUBERCULOSIS.

AT the annual meeting of the Hospital Saturday Fund held on April 28th, Dr. Arthur C. Latham drew attention to several important points in the treatment of tuberculosis amongst the industrial classes. The value of the sanatorium treatment is now generally recognised but there are certain facts connected with it that have not been sufficiently appreciated by the laity, more particularly amongst the working classes. The first is the importance of an early diagnosis; secondly, that a sufficient time must be devoted to treatment; and thirdly, that after leaving the sanatorium an outdoor occupation must be adopted. The difficulties of carrying out these recommendations will be at once obvious. Dr. Latham maintains that the charitable institutions which deal more particularly with tuberculosis are not established on right principles in this country and there is doubtless much to be said in support of this contention. He states that if the full economic value of the money spent in the treatment of tuberculosis is to be obtained the following reforms are essential: 1. There should be a number of institutions, municipal or other, such as the French dispensaries, where, on payment of a small fee, any working man or woman in a suspicious state of health could have the expectoration examined—this plan greatly facilitates the early recognition of the disease. 2. All hospitals should be brought into close connexion with the various organisations which exist for the relief of the poor, so that the patients can be assisted in obtaining admission to special institutions. 3. The "pernicious system" of in- and out-patient letters to the hospitals should be discarded and "cases should be admitted on their merits." The point thus raised is an important one but is so involved that we cannot enter into a discussion on it here. 4. Every "consumption hospital" should be in close touch with sanatoriums in the country to which patients could be sent from the town hospitals. If these proposals were carried out some of the difficulties which now exist would be removed but others would remain. One of the chief of these is the support of families whilst the bread-winners are in the sanatorium. As soon as a patient finds that he is improving he is naturally anxious to return to work so as to earn money for those dependent on him and so he leaves the institution before the processes of repair are satisfactorily established. Dr. Latham referred to the well-known German methods of insurance but expressed his belief that this plan would not be adopted in England. He therefore made an appeal to the friendly and allied societies to take the matter up for the benefit of their members. He believed that these societies have the money and the necessary organisation. He stated that a beginning had already been made and that the friendly societies of the Midland counties have formed an association for this purpose. He also referred to the National Committee for the Establishment of Sanatoria for Workers which has been formed at the initiative of the Hospital Saturday Fund. The friendly societies, Post-office employés, trade unions, employers of labour, and all other classes interested in the subject are invited to coöperate. Such an organisation is likely to be most valuable and we wish it every success. Dr. Latham's address was a practical and suggestive one and doubtless it will receive due attention.

EPSOM COLLEGE.

WE have received from Dr. J. H. Galton, the chairman of the finance committee of Epsom College, an appeal on behalf of the benevolent side of the institution. As most of our readers are aware, the College gives gratuitously to 50 sons of medical men in necessitous circumstances a first-class education, with board, clothing, and maintenance, and provides pensions of £30 a year for 50 poor aged medical men or the widows of those deceased. The pressure of unexpected heavy sanitary expenses has so crippled the resources of the College that the council has been compelled to increase the mortgage from £10,000 to £14,000 and to incur a debt of £2000, money advanced for immediate necessities by the bankers. Last year a sum of £1600 was spent on account of repairing and renewing the drainage system of the College and it is estimated that a further sum of £3300 will have to be expended in order to bring the sanitary condition to that degree of perfection which should exist in the case of a college governed by a council chiefly composed of medical men. It is hardly necessary to state that the present governing body is in no way responsible for the condition of affairs which has necessitated this enormous expenditure; perhaps no past council can be fairly considered to be answerable, since the system of laying drains in vogue from 30 to 50 years ago was primitive compared with the rigid requirements of our present sanitary authorities. The council considers the present year, when the jubilee of the opening of the College is to be celebrated by old Epsomians, to be an excellent occasion for making a strenuous effort to wipe away the indebtedness of £16,000. The amount is trivial compared with the sums appealed for by other charities and if the majority of medical men, in whose interest the institution was founded by Mr. Propert, were to make a genuine effort to procure this sum the College would be freed from debt, perhaps for ever. When it is recollected that there are over 38,000 medical men on the Register it will be seen that not much self-sacrifice is required on the part of each member of the profession to raise the sum of £16,000. Few persons can be more fully aware than we are of the slender incomes of very many members of the profession, but we are as fully aware of the good work done by the benevolent side of Epsom College, and know that a restriction of this work would be little short of a calamity, since it would tax the already overstrained funds of the other benevolent agencies of the profession. The council has issued with the appeal a list of the educational successes which have been gained since 1893 and these for a school of about 240 boys are most satisfactory. No fewer than 24 open scholarships have been gained at the Universities of Oxford and Cambridge; 140 boys have passed the matriculation examination of the University of London, 80 of whom were in Division 1; 38 boys have passed the preliminary scientific examination for the degree of M.B of the University of London, and 41 boys have passed a part of that examination; 88 higher certificates of the Oxford and Cambridge Schools Examination Board, with 23 distinctions, and 293 lower certificates have been gained. The fee charged for boarders is 75 guineas a year but all sons of medical men are allowed a reduction of ten guineas. Day boys are charged 25 guineas, and sons of less fortunate members of the profession can compete for "council exhibitions," which reduce the fee from 65 guineas to 35 guineas. There are also open entrance scholarships awarded annually of the value of £30 a year. The work of the council in steering the College through the numerous financial difficulties which have arisen during the past few years has been onerous in the extreme and no one has worked with greater energy than the treasurer, Sir Constantine Holman. It is to be hoped, therefore, that all friends of the College, especially old boys who have benefited by the sound education provided at a moderate fee, will come to the assistance of the council and the treasurer at the present time when funds are so urgently needed.

ANNUAL REPORTS OF THE PROGRESS OF CHEMISTRY.

THE decision of the council of the Chemical Society to issue a systematic series of reports in English on the progress of chemistry in its several divisions and applications will be cordially welcomed. Practical effect has already been given to this decision, for we have recently received a copy of the Annual Report on the Progress of Chemistry for 1904.[1] We heartily congratulate the Chemical Society on the fulfilment of the scheme and, judging by the first volume, it is quite clear to us that these annual reports will be of extreme value. In the words of Dr. W. A. Tilden, in his introduction to the report, the object of the reports is to present an epitome of the principal definite steps in advance which have been accomplished in the preceding year for the benefit of all workers, students, or teachers of chemistry, or those chemists who are engaged in technical or manufacturing applications of chemistry. Thus those who make a special study of any one department of the science may obtain without difficulty information as to the nature and extent of progress in other branches of the subject to which they have not paid special attention. In accordance with this object the council invited the assistance of a number of gentlemen distinguished for their acquaintance with the several divisions of the subject and the result is a series of reports contributed by admitted authorities on the various sections of the science. Necessarily the report cannot be placed in the hands of the Fellows of the society until a month or so after the close of the year. In the report just published, which deals with the progress of chemistry for 1904, ten articles are contributed. The first is by James Walker, D.Sc., Ph.D., F.R.S., on General and Physical Chemistry, in which he deals, amongst other things, with the researches of the year on colloidal solutions, fluid crystals, catalysis, enzyme action, and passivity of metals. The second article, on Inorganic Chemistry, is written by P. Phillips Bedson, M.A., D.Sc., and consists of an admirable *résumé* of the year's contribution to the chemistry of the inorganic elements. Organic chemistry comes next and is divided into two sections, the aliphatic series by H. J. H. Fenton, M A., F.R.S., and the aromatic series by Julius B. Cohen, Ph.D. The article on Stereo-Chemistry is by William Jackson Pope, F.R S., F I.C.; that on Analytical Chemistry by A. C. Chapman, F.I.C.; that on Physiological Chemistry by W. D. Halliburton, M D, F.R.C.S.; that on Agricultural Chemistry and Vegetable Physiology by J. A. Voelcker, M.A., Ph.D; that on Mineralogical Chemistry by A. Hutchison, M.A., Ph.D; and the last article on Radio-Activity is by Frederick Soddy, M.A. These articles all afford extremely interesting reading and the whole scheme will be most helpful to those who desire to keep *au courant* with the trend of modern research.

THE "CHINESE SPY" ON MEDICINE AND SURGERY.

THE "Chinaman" who has recently so severely satirised America's love of quackery may have drawn the idea of his theme from the "Chinese Spy," a work published so long ago as 1766. In Letter XIII., Book VI., of the "Chinese Spy," the mandarin Cham-pi-pi, writing from London to his friend, Kie-tou-na, in Peking, draws a gloomy picture of the state of contemporary science and denounces medicine and surgery with an acrimony impartially used by the satirists of the eighteenth century towards all medical men, whether good or bad. "This letter," he says, "shall be taken up with physic, that dreadful science, which has got the life of man within its gripe. There are companies in Europe who have a licence to kill: these sentences of death are called a 'physician's prescription. The practice of this science is thus: A man in black, of a solemn deportment, comes into a sick person's chamber: after asking some questions concerning his illness, he writes down on a paper the medicaments proper for curing him; and a few days after the death of the patient, this black man comes and asks payment for his cure: nay, there are countries in Europe where a dead person cannot be buried, till the physician who killed him be paid. The annals of the universe inform us, that anciently only one family was acquainted with physic; and greatly is it to be wished, for the sake of mankind, that this science was still a family-secret. At present, any one who pleases may practise physic; and all the mystery is, to learn, in a few years, the cures of all kinds of distempers. This science has been rendered more destructive by adding to it surgery, which is the art of slashing bodies and dissecting carcasses.' Physicians, in order to come at a knowledge of the human body, cut it into a thousand pieces; and, besides shortening the life of men, they kill them a second time when dead. Europeans will very gravely ask, whether we can do without physicians? This is asking, in other words, whether God has created a nature so imperfect, that it cannot subsist without the help of art. What physicians have animals? This decides the question. The annals of the Christian religion mention a king, named Hezekiah, who suppressed a book on the virtues of plants, lest it might come into use, and thus multiply distempers: it were proper to suppress physic, that everybody, having no other recourse, might become his own physician." Who was the "Chinese Spy"? Could he spastic. According to these writers if flaccidity persists there is not only transverse division of the cord but destruction of the nerve centres in the lumbar region. The observation showed that these centres were not destroyed. Faradic and galvanic stimulation of the muscles was prescribed so as to keep them in as healthy a condition as possible. After six months the flaccid paralysis persisted, showing the correctness of Dr. Bastian's view and proving for the first time on record that permanent flaccid paralysis and loss of reflexes are due to removal of the influence of the higher centres and not to any concomitant injury of the lumbar centres. 11 months after the operation the recent work which had been done on the regeneration of nerves, showing that transplantation of peripheral nerves might be successfully performed, suggested to Dr. Shirres that the transplantation of a piece of a dog's cord might be tried in this case. The spinal cord of a large dog was exposed under chloroform while the operation on the patient proceeded. The lesion was exposed and the gap between the ends of the cord was found to be now one and a half inches. With a mild faradic current the anterior and posterior roots of the cord were stimulated and a slight response was obtained in the muscles. Three inches of the dog's cord were placed in the gap and the pia arachnoid was united to that of the patient by a few fine stitches. The dura mater was closed, the wound was sutured, and a plaster jacket was applied. Perfect recovery from the operation took place and the temperature never rose above 100° F. In the fifth week after the operation the patient was conscious of flatus in the lower part of the abdomen, a sensation which he never had before the operation. Six days later he felt the passage of the catheter when the usual lavage of the bladder was performed. Ten days later he was conscious that his bowels were about to act and he felt a sensation of pins and needles in the right foot. A week later he felt the same in the left foot. The temperature rose to 103° and the patient began to fail. After a fortnight he died. A large abscess was found in the right kidney and appeared to have been the cause of death. The cord was removed and hardened in Müller's fluid. After six weeks the dura mater was opened and a diffluent mass was found between the ends of the cord. Sections were made above and below the lesion and through the dura mater and adherent mass between the ends of the cord and stained by the Pal-Weigert method. The usual ascending and descending degenerations were found. In the intermediate mass minute myelin sheaths of nerve fibres were demonstrated closely adherent to the dura mater and were traced upwards and downwards into the ends of the cord, showing that some regeneration had taken place. Dr. Shirres does not assert that the piece of dog's cord lived or that it started the regeneration. His case at least suggests that something might be done in cases of division of the cord to favour regeneration of the fibres. Dr. James Collier, in a recent paper published in *Brain*, states that experiments on animals show that after immediate suture of the cord regeneration is possible.

---

THE ASSOCIATION OF ECONOMIC BIOLOGISTS.

THE first congress of the above-named association was held on April 19th and 20th in the University of Birmingham, Mr. F. V. Theobald, the President, being in the chair. As the term "economic biology" is not very widely known we may state that it applies to the study of biology in reference to the application of that study with regard to its bearings on agriculture and incidentally to the arts. Long ago Darwin applied the principles of economic biology in his famous dictum that the facilities for the growth of a certain kind of clover depended on the number of old maids in any given district. The clover in question could only be fertilised by a certain kind of bee; the larvæ of this bee were eaten by a certain kind of field mouse which in its turn was eaten by cats and these cats as a rule were kept by old maids. So we find the economic biologists discussing the vagaries of the life of the hop aphis, and the President in his paper on the subject pointed out that the great thing for the hop farmer to do to preserve his hops from this aphis was to "wash his damsons early in the year and use drastic measures in destroying the hedgerows of sloe." Another interesting paper was one read by Mr. Herbert Stone on the Porosity of Wood which led up to a discussion on the best means of seasoning timber. Dr. Macdougall addressed the meeting on a parasite of the sheep, Lucilia Sericata. In the course of his paper he threw doubts upon the usefulness of the starling as a "*sanitary inspector of sheep.*" As regards this question he had received from two widely separated districts of Scotland information from men whose opinion he valued that they traced the increase in the prevalence of sheep fly to the enormous increase in the quantity of starlings, and they suggested that the fly was attracted by the excreta which the starlings left on the sheep's backs. We should hardly think that this suggestion is plausible for the excreta of birds is mainly made up of uric acid and phosphates and would not be likely to attract a fly, more especially one the larvæ of which do not feed on excreta but live in animal tissues. If the starlings do eat the grubs of the fly we should have thought that the increase in the number of birds was the effect of an increase in the number of flies and not the contrary. The concluding paper of what seems to have been a most interesting meeting was by the President on Ticks and Flies as Agents in the Distribution of Disease; this paper will be published *in extenso*.

AORTIC REGURGITATION WITH ANGINA; LICHEN ON THE PAINFUL AREAS.

THE areas of skin in which the pain of angina pectoris is felt usually show no objective phenomenon. At the meeting of the Société Médicale des Hôpitaux de Paris on March 31st M. Gasne and M. Chiray reported the following remarkable case in which lichen planus appeared. A man, aged 31 years, was admitted into hospital. He was addicted to alcohol and had suffered from malaria, dysentery, and acute rheumatism. In October, 1904, he began to suffer from cardiac palpitation and a feeling of pulsation in the neck and the temples. In November these symptoms were increased and a constant uncomfortable sensation was felt in the præcordium which at times gave place to a severe and constrictive pain which had never the characters of definite angina, for it was not accompanied by a feeling of impending death but by one of vertigo and did not instantly cause immobility of the body. During the paroxysms the pain radiated into the left arm along its internal aspect as far as the fingers and was accompanied by a feeling of numbness. The whole arm became very warm and the veins dilated. These attacks occurred three or four times a week. On examination the apex beat was found in the sixth intercostal space and was abnormally strong. There were a diastolic aortic murmur and other signs of aortic regurgitation. The patient, who had always been very neurotic, had felt for two months acute sensations of itching, especially on the internal surface of the left arm. He had scratched himself considerably and on the pruriginous patches there were areas of lichen. There were four patches in a linear series along the internal surface of the upper arm corresponding to the distribution of the intercosto-humeral nerve. Above and outside the left nipple, in the area in which the intercostal nerves anastomose with this nerve, was another small patch. On the rest of the body only acne was observed, except in the right popliteal space where there were some spots of lichen planus. The whole of the area of distribution of the intercosto-humeral nerve was hyperæsthetic to touch and to heat. The affected area consisted of a band on the inner surface of the upper arm and an area on the thorax extending from the third to the fourth intercostal space and from a vertical line passing two fingers' breadth outside the nipple to the posterior axillary line. M. Gasne and M. Chiray suggested that the neurotic condition of the patient predisposed him to lichen which was localised in the distribution of the intercosto-humeral nerve and its intercostal anastomoses. They thought that this localisation was due to reflex irritation provoked by the crises of angina. Such localisation is easily explained. Dr. Henry Head has put forward the view that the angina of aortic regurgitation is due to irritation of the cardiac nerves from the high intraventricular tension. According to Dr. G. A. Gibson the greater part of the cardiac plexus is furnished by the left inferior cardiac nerve —i.e., by the left inferior cervical ganglion of the sympathetic. This ganglion receives branches from the segments of the cord whence arise the eighth cervical and the first and the second dorsal nerves. From the same segments arise also the fibres of the intercosto-humeral nerve. Thus the localisation of the pain and the eruption is explained.

A SUGGESTION IN PRISON REFORM FROM FRANCE.

IN our issue of August 20th, 1904, we commented upon an experiment in prison reform carried out by Miss Charlotte Smith-Rossie. The experiment was that of giving fortnightly lectures upon sanitary subjects to women prisoners in Portsmouth prison. So successful was this work that we learn that by direction of the Home Secretary a complete system of lectures on hygiene has now been initiated at Holloway prison. Miss Smith-Rossie has lately been studying a different section of prison life in France and has been permitted to visit the children's prison of La Roquette —i.e., the Petite Roquette. The regulations under which children can be imprisoned in France differ widely from those which obtain here, but that is not the point which we wish to notice. Miss Smith-Rossie in her article, which appears in the May number of *Good Words*, lays special stress upon the way in which French child prisoners work. The reason of their doing good work and of their taking an interest in their work is that they are paid "a small sum daily in proportion to the work done, which sum can be at once spent by the prisoner himself within the prison." Work for work's sake may be all very well when the worker labours for himself, but to work for someone else without getting any credit for it takes all the heart out of the worker and we think that the French system might be adopted in our own prisons.

THE annual meeting of the Asylum Workers' Association will be held at the rooms of the Royal Medical and Chirurgical Society, 20, Hanover-square, London, W., on Friday, May 19th, at 4 P.M. with Sir John Batty Tuke, M.P., President of the Association, in the chair. The Archbishop of Canterbury has promised to attend and there will be a presentation of two gold and two silver medals awarded by the association for long and meritorious nursing service. All interested in asylum work and workers are cordially invited to attend the meeting of this association which was founded in 1895 to improve the status of asylum nurses and attendants, to provide for them "Homes of Rest and Nursing," and to enlist public sympathy in their work.

THE Glasgow University Club, London, will dine at the Trocadéro Restaurant, Shaftesbury-avenue, London, W., on Friday, May 26th, at 7.15 P.M., when Professor Sir William Ramsay, K.C.B., will occupy the chair. Members of the club who intend to be present or to introduce guests are requested to give notice as early as possible to the honorary secretaries, Dr. James M. Dodds and Dr. C. O. Hawthorne, at 63, Harley-street, W. The annual general meeting of the club will be held at the same place and on the same date at 6.45 P.M.

THE opening lecture of the summer session of the North-East London Post-Graduate College will be given by Dr. H. D. Rolleston, physician to St. George's Hospital, on Thursday, May 11th, at 4 30 P.M., at the Tottenham Hospital, London, N., on High Arterial Tension, its Results and Prevention. The series of clinical lectures, of which this is the first for the present session, is free to all qualified medical practitioners.

THE eighth annual meeting of the Childhood Society will be held at 7, St. James's-square, London, S.W., on Wednesday, May 10th, when an address on Teaching "*Commonsense*" in the School of the Future will be delivered by Professor H. E. Armstrong, Ph.D., LL.D., F.R.S. The chair will be taken at 3 P.M. by the President, Earl Egerton of Tatton.

THE May dinner of the Aberdeen University Club, London, will be held at the Trocadéro Restaurant on Wednesday, May 17th, at 7.30 P.M. The Very Rev. John Marshall Lang, D.D., principal of the University of Aberdeen, will be in the chair. Members desiring to be present should communicate with Dr. R. J. Collie, honorary secretary, 25, Porchester-terrace, W., not later than May 13th.

THE discussion at the Epidemiological Society arising out of Dr. G. S. Buchanan's paper on the Spread of Small-pox occasioned by Small-pox Hospitals during 1900–04, which was read before the society on Friday last, will be continued to-night (Friday) by Dr. Arthur Newsholme at 11, Chandos-street, Cavendish-square, at 8.30 P.M.

THE annual dinner in connexion with the West London Hospital and Post-Graduate College will be held at the Trocadéro Restaurant on Wednesday, June 7th, at 7 o'clock, Dr. Seymour Taylor presiding. All information can be obtained from the Dean of the Post-Graduate College, Hammersmith, W.

THE Lord Mayor will preside at a public meeting at the Mansion House on May 17th, at 3 P.M. The meeting will be in support of an appeal for £10,000, which sum is urgently required by the National Association for the Prevention of Consumption and Other Forms of Tuberculosis.

AT the meeting of the Medical Society of London to be held on Monday, May 8th, there will be a discussion on the Perineal and Suprapubic Methods of Prostatectomy, to be opened by Mr. Reginald Harrison.

Professor Groedel of Nauheim requests us to contradict certain alarming reports which have been circulated as to the state of his health. We are happy to be informed that he is quite well.

THE Lord Mayor is announced to take the chair at a festival dinner to be held at the Trocadéro Restaurant in aid of the funds of the City of London Hospital for Diseases of the Chest, on Friday, May 26th.

THE next session of the General Council of Medical Education and Registration will begin on Tuesday, May 23rd, at 2 o'clock P.M.

when the medical officer of such a burgh dies or resigns the result not infrequently is that the county medical officer is appointed, so that the influence and sphere of work of the professed sanitarian tend to increase.

The duties of a county medical officer are not the same in Scotland as in England. In Scotland he is the executive and administrative officer. He is so not because he is county medical officer, but because every county medical officer is also medical officer for the districts under the charge of the district committees of the county councils. These district *committees themselves are the local authorities under the* Public Health Act, and when a man is appointed county medical officer he is also appointed medical officer for the districts of the county, these districts not including the burghs. Each district committee consists of the members of the county council resident in that district and also of a representative from each parish council in the district. The police burghs have representatives on the county councils, and also therefore on the district committees, but they do not act in public health matters as the burghs are not rated for public health by the county council, each burgh having charge of its own public health. As already stated, however, the county and district medical officer may hold burghal appointments also, but the custom is that the larger burghs have their own medical officers.

It is compulsory on every county to have a medical officer of health and the appointments are permanent in the sense already explained. Nearly all the county medical officers are "whole time" men. In the largest burghs also the medical officers are not in general practice, but several of them hold other appointments more or less related to public health. In the smaller burghs the medical officers are usually engaged in private practice unless it should occur that the county medical officer holds the appointment. This is a position which tends to occur more frequently and is of good omen, as it implies a general improvement in salary, for the range of salaries in Scotland is not so good as it is in England, although it is improving. The Poor-law medical officers, as such, have no sanitary duties in Scotland (excepting vaccination of defaulters), and have no security of tenure, but attempts are being made to obtain this by legislation. Their position at present is in this respect a very unfortunate one. The areas controlled by the district committees of the Scottish county councils are in most cases sufficiently large to prevent local influences having sway, especially as the medical officers are not engaged in private practice and have security of tenure over fixed areas. The smaller burghs are the worst off on the whole because their areas are limited and local influences consequently have more weight. Their medical officers have of necessity only small salaries, so that a mere fraction of their income represents their public work and their private practice is of supreme consequence to them. Everything that has already been said about the undertaking by English medical officers of health in rural districts of both public and private duties can be said concerning the Scottish medical officer of health when doubly employed, but the northerners have the best of the situation. They cannot be dismissed excepting with the approval of the Local Government Board. That Board has control of the distribution of a Government grant towards the salaries of medical officers of health and sanitary inspectors. It has power to refuse the grant if local arrangements are unsatisfactory. At present the grant, which is a fixed sum of £15,000 per annum, contributes about 7*s.* 6*d.* per £ to salaries and travelling expenses. The salaries for whole time medical officers range from about £350 or £400 to about £850, exclusive of travelling expenses and other outlays.

It will be seen that the sanitary services in the three countries have certain points in common. Where the countryside is sparsely populated and the districts are poor no funds for the payment of a medical officer of health are available. It is true that such districts escape risks which have to be taken by more crowded communities but it is none the less dangerous that they should be left without proper sanitary inspection and control. In Ireland this ineffectiveness of the sanitary administration is only part of the deplorable condition of the dispensary medical service and the remedies to be taken for the abuses are the remedies which should be applied to the reform of that service, which will be suggested in dealing with the administration of the Poor-law in the three countries. In England we have a much more crowded country with a much higher general standard of wealth. There is no reason, in theory, why England should not have a capable and fearless sanitary administration, but in practice the law is against it. In which attitude the law is also against much public and official opinion. When Sir Walter Foster was Parliamentary Secretary to the Local Government Board, now nine years ago, he spoke as follows to a deputation that had represented to him the inconvenience of placing the medical officer of health in a position where he is at the mercy of ignorant caprice:—

> The Board has arrived at a rather important decision—viz., that we *consider these appointments for short periods and precarious* tenure injurious to the public health. We are at one with you that men holding appointments for very limited periods cannot be expected to discharge their duties in that fearless and thorough manner which those duties require for the safety of the public, and we are anxious to encourage local authorities to give up the system of short appointments. We recogn [illegible] re very delicate and difficult, as well as exceedi [illegible] hile a man is elected from year to year by a [illegible] may be offended by his zeal for the public health, we feel he cannot discharge his duties in the way they ought to be discharged. We have, therefore, arrived at the decision that we shall encourage local authorities all over the country to make these appointments for longer periods and, if possible, permanent appointments.

These be brave words, but as yet they remain largely words. The Local Government Board has done something towards their fulfilment and is still doing something; but reform comes very slowly. Fixity of tenure is more likely to follow upon the general appointment of county medical officers than upon the recommendation of the Local Government Board to certain authorities that certain individual medical officers of health should not have a term set to their period of office.

(To be continued.)

ERRATUM.—It has been pointed out to me that certain errors of detail have been committed in my description of the conditions under which naval medical officers discharge their duties. I have not given sufficient credit to the department for the reforms effected in the warrant of 1903. The cost of the post-graduate course, which is now required of every medical officer, is in the first instance defrayed by the officer, as I said, but the £25 is repaid to him by the Admiralty immediately he produces the necessary certificates of attendance. The comparison of charge pay in the navy with charge pay in the army cannot be made as I made it, as charge pay is given to deputy-inspector-generals, fleet-surgeons, and staff-surgeons, as well as to inspector-generals. The rate of payment is in correspondence with the rank of the officer, being 10*s.* per diem for an inspector-general, 7*s.* 6*d.* for a deputy-inspector-general, 5*s.* for a fleet-surgeon, and 2*s.* 6*d.* for a staff-surgeon. Charge pay is received in addition to "hospital allowance" by officers in charge of hospitals. All naval medical officers who are in hospitals, dockyards, marine infirmaries, or at the Admiralty receive "hospital allowance," and any officer not in official quarters receives "house allowance" in addition, but the charge pay of those in charge of hospitals is not received *in lieu* of "hospital allowance" but *in addition to* "hospital allowance." I regret that I did not perceive the full extent of the reforms which have recently taken place in the Naval Medical Service, as I desired particularly to bring before the notice of the medical profession what a good career that of a naval medical officer now is. The Admiralty provides a modern and expensive scientific equipment for its medical officers, great pains have been taken to attract young men of promise in their profession, and I am certain that these pains will be rewarded.—THE WRITER OF THE ARTICLE.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on April 27th, Sir R. DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced that, in accordance with the resolution passed at the last Comitia, he had nominated the following Fellows to serve on a committee appointed to consider the increasing mortality from plague:—Dr. J. F. Payne, Dr. Norman Moore, Sir Patrick Manson, Dr. John Anderson, Dr. W. J. R. Simpson, and Dr. W. B. Beatson. He also stated that he had nominated Sir Dyce Duckworth to represent the College at the International Congress of Medicine to be held at Lisbon in April, 1906.

The PRESIDENT drew attention to the fact that Sir William S Church, as President of the College, had been a member of, and chairman of, the Cancer Research Committee and in retiring from the position of President thereby was no longer a member of that committee It was therefore resolved to request Sir William Church to continue a member of the Cancer Research Committee

SIR WILLIAM CHURCH thanked the College for the resolution and acceded to the wishes of the Fellows

The report of the Committee on the Care and Control of the Feeble Minded was received and adopted

The following gentlemen having passed the required examination were admitted as Members of the College Arthur John Jex Blake, M A, M B Oxon, Frank Edward Taylor, M A Vict, M B Lond, L R C P, George William Watson M D Lond, L R C P, and William Henry Wynn, M D Lond, L R C P

The following Members were elected as Fellows of the College Duncan Burgess, M B Cantab, Thomas Watts Eden M D Edin, Wilfred John Harris, M D Cantab, Bedford Pierce M D Lond, Leonard Rogers, M D Lond, I M S, James William Russell, M D Cantab, James Harry Sequeira, M D Lond, Harold Batty Shaw, M D Lond, Edmund Ivens Spriggs, M D Lond, William Barnett Warrington M D Lond, Arthur Whitfield, M D Lond, and Robert Arthur Young, M D Lond

The following communications were received 1 From the secretary of the Royal College of Surgeons of England, reporting certain proceedings of the Council on April 13th 2 From the executors of the late Mrs Begley, announcing a bequest of £500 to the College

Dr P H Pye Smith was re elected the representative of the College on the Senate of the University of London

On the recommendation of the Council the Baly medal was awarded to Professor Pavlov of St Petersburg, as having pre eminently distinguished himself in the science of physiology

The quarterly report, dated April 7th, of the College finance committee was received and adopted

A report, dated Feb 6th, was received from the committee of management Amongst other matters it was recommended that the Swansea General and Eye Hospital should be added to the list of general hospitals recognised by the Examining Board in England and that the Willesden District Isolation Hospital should be added to the list of fever hospitals recognised by the Examining Board in England

A report, dated Jan 27th was received from the laboratories committee

A report was received from Dr Pye Smith on the history and the work of the laboratories of the Royal Colleges since their opening in January, 1890 A vote of thanks was accorded to Dr Pye Smith for the report

A report was received from Sir William Church and Sir Lauder Brunton on the conference of the Royal Sanitary Institute on School Hygiene, held from Feb 7th to 10th, 1905

Dr NORMAN MOORE proposed the following motion —

> That a generous offer of the Worshipful Company of Barbers conveyed in a letter to one of the Censors to restore to the College an Inspeximus Charter of Charles II now in possession of the Company be accepted

This was seconded by the SECOND CENSOR (Dr W H ALLCHIN) and carried Dr Norman Moore was requested to receive the charter

A list of books and other publications presented to the library during the past quarter was received and thanks were returned to the donors

The PRESIDENT *then dissolved the Comitia*

EGYPT IN 1904.

THE Earl of Cromer's report on the Finances Administration and the Condition of Egypt and the Soudan in 1904 is a lengthy document covering about 150 pages of fool cap size but the contents, generally speaking, are full of interest and many subjects are dealt with that appeal specially to the sanitarian The Nile flood of 1904 was but little better than that of 1902, which was the lowest but one of those recorded but notwithstanding this serious drawback which a few years ago would have entailed great scarcity, if not actually a famine, Lord Cromer is able in his concluding paragraphs to state that the past year was one of unexampled prosperity in Egypt in spite of the ravages of the cattle plague and the fact that the cotton crop was a partial failure Elsewhere he writes that the situation was saved by the works constructed during recent years and by the zeal and ability of the irrigation staff, and he further expresses the opinion that the whole population of Egypt owe a deep debt of gratitude both to these officials and to their predecessors

The revenue of Egypt in 1904 amounted to £E 13 906,152, being no less than £E 2,406 152 in excess of the estimate As, however, the expenditure was also largely in excess of previsions the actual surplus only amounted to £E 1 205 820 For the current year the estimated revenue is £E 12 255 000 and the estimated expenditure £E 11,755 000 the anticipated surplus consequently amounting to £E 500 000 a sum which we believe to be by far the largest that has ever appeared under this heading Lord Cromer considers it to be highly satisfactory that whilst *maintaining the policy of slow progress and low taxation* it has been found possible to increase the administrative expenditure by no less in round figures, than £E 630,000 Of this sum the lion's share is absorbed by the public works department, less than a tenth of the whole being distributed between the police, the prisons, and the sanitary services "I am prepared to admit," continues Lord Cromer, "that it might have been possible, without serious risk of disturbing financial equilibrium, to go somewhat further in the direction of either reducing taxation or of increasing expenditure But I repeat that, after full consideration it was thought wiser to move tentatively and cautiously in the inauguration of the new system and to contemplate the possibility that either by reason of a heavy fall in the price of cotton or from other causes the rapidly growing prosperity of the country might receive a *check* " Under the "*new system*" of financial control which has become possible since the signature of the Anglo French Agreement in April, 1904, the assets of the General Reserve Fund on Jan 1st last amounted to £E 13 376 146 Of this large sum £E 7,529 074 have been hypothecated in various ways but there still remains a balance of £E 5 847 072 which is available for capital expenditure of various sorts whether in Egypt or the Soudan The fund also, will be replenished by the surplus of 1905 and also by about £E 3 000 000 from the liquidation of the Daira estates

Under these flourishing financial conditions it is to be regretted that the question of town sewerage should have been allowed to fall into abeyance Throughout his long report Lord Cromer makes no mention whatever of drainage, although he admits that only the fringe of the great question of sanitation has yet been touched in Egypt In 1890 he wrote that the only way to remedy this evil was to construct a system of sewers on scientific principles An eminent English engineer, Mr Baldwin Latham, had been specially deputed some little time previously to report fully on this subject The plan which he framed, and which Lord Cromer approved of, would have cost about £700 000 In his book "England in Egypt" Viscount Milner also alluded to this project, saying that the revival of interest in sanitary matters was further proved by the preparation then being made for the thorough drainage of Cairo It is difficult to understand the complete shelving of this important matter, for in 1898, under the heading "Drainage of Cairo," Lord Cromer wrote

"This subject has been under consideration since 1890 but owing to financial and other reasons no solution has so far been found The *Cairo Water Company has now in hand* a scheme which is almost ready to be submitted to the Government The approximate total cost is £E 750 000 It is to be hoped that at no very distant date it will be possible to commence work I may mention that in 1891 the Powers agreed to the administrative expenditure of the Egyptian Government being increased by half the Octroi receipts of Cairo in order to provide for the drainage of the town The financial difficulties of carrying out any scheme are thus materially lessened That sewerage is urgently required not only in Cairo and Alexandria but also in the large towns of Upper Egypt (where the Nile receives most of the filth) as well as in those of the Delta cannot be seriously contested The number of towns which are provided with an abundant water supply is being steadily added to but in no case are there channels for its removal when soiled Closets and sinks discharge causing great embarrassment to those who so generously propose to entertain parties at Vichy and Evian and at the watering-places of Béarn. It is therefore particularly requested that the slip as to the excursions may be filled up and returned at once. Our readers may be reminded that it will be possible to return direct from Vichy to Paris on Monday, May 15th.

Among the demonstrations and lectures to be given will be one in English by Dr. H. Mendel on Intra-tracheal Injections. The demonstration will be given in the St. Charles Salon of the Hôtel Dieu on Friday, May 12th, at 10 A.M. Dr. Mendel will demonstrate his own method of giving intra-tracheal injections, the chief point of which is that he uses non-irritating substances so that no reflex cough is produced. Dr. J. Rivière will be pleased to receive any of his British colleagues and to show them the Establishment of Physicotherapy at 25, Rue des Mathurins (Opéra) during the visit from 10 A.M. to midday and from 2 to 6 P.M., except on the afternoon of Friday, May 12th.

MEDICINE AND THE LAW.

The Scope of Scientific Testimony.

Dr. Solomon Solis Cohen, professor of clinical medicine in the Jefferson Medical College, in an address delivered before the Philadelphia College of Pharmacy and published in the *American Journal of Pharmacy* for January, has recently discussed the scope of so called expert evidence in trials from the ethical point of view. The correct attitude of an expert witness is well summed up by Dr. Cohen in the following passage: "As a witness he is bound by his oath and by his duty to the court and to the State to endeavour to assist judge and jury to reach correct conclusions without reference to the effect of those conclusions upon the verdict to be rendered. He is to distort nothing, magnify nothing, minimise nothing; assert as positive nothing doubtful, throw doubt upon nothing certain; introduce nothing irrelevant, suppress nothing material; give utterance to no statement of fact, advance no theory that he would shrink from defending before a learned society." Dr. Cohen proceeded to enumerate the many difficulties that a scientific witness meets with in the courts and laid stress on the necessity of avoiding the position of partisan, whether from a personal though disinterested desire for the success of one side or from the pertinacity of advocates or from a mistaken notion that the acceptance of a fee by a scientific witness puts him under an obligation to strain the evidence as far as possible in favour of his own side. Any such false position can be avoided by making certain stipulations when called upon to consider the facts in a given case. The suggested stipulations are: (1) that there is no obligation for the expert to testify or to give counsel involved in his acceptance of a fee to examine papers or otherwise look into the facts; (2) that the nature of the testimony to be given, in case the preliminary examination permits an agreement to testify at all, is subject to modification by the subsequent disclosure of new facts at the trial or otherwise and that the attorney must then decide for himself whether or not to call the expert as a witness; (3) that he is to be asked only simple and direct questions permitting the framing of answers that will bring out the whole truth as one sees it and not merely fragments of the truth; (4) that he is not expected to be positive upon uncertain matters or to throw doubt upon those that are not doubtful; and (5) that he is not to be asked questions to which correct answers must be highly technical simply for the purpose of obscuring the issue. By taking such a course of action scientific witnesses would avoid being placed, even apparently, in the position of partisans or scientific advocates. The function of a scientific witness is to enlighten the judge and the jury as to the significance of certain facts and relations beyond the ordinary knowledge but of which he has made a special study. His testimony must be based in part upon his reading and in part upon his observations. Expert witnesses upon pharmacological questions are called upon to give four different orders of testimony not usually discriminated. They are all treated as matters of opinion but in reality three relate to matters of fact and may be distinguished as follows. 1. Personal observations on the part of the witness as to the effect of drugs on the human or the animal body. 2. The methods of chemical analysis and their results. That arsenic has or has not been found is a matter of fact and is to be criticised from that standpoint. If the methods pursued have been faulty, or if the results have been inconclusive, that can properly be shown, but also as matters of fact and not of opinion. It is perfectly proper to point out, for example, that in the attempted identification of poisons a careless observer may mistake antimony for arsenic, but it is misleading to attempt to make a jury believe that discrimination between antimony and arsenic is at all uncertain when the right tests have been made. 3. Matters of general scientific knowledge —e.g., as to the action of drugs or the contamination of foods, drugs, and manufactured articles of various kinds, by poisons, or as to chemical and pharmaceutical incompatibilities—are also matters of fact, whether within or without the personal observation of the witness. Concerning matters, however, which are not only outside the observation of the witness but beyond the range of his usual studies he can only have an opinion. He cannot know them as facts and he should refuse to testify concerning them. Again, in a case of suspected poisoning a medical practitioner who has not seen the living person or the corpse can only be asked to express an opinion on facts described by others as to the nature of symptoms during life and as to the cause of death, for the facts are all beyond his knowledge. These views of Dr. Cohen are of interest to medical men who as a body are so often called upon to give evidence in the courts, evidence on which may hang the life or liberty of a fellow subject. It is impossible to magnify the importance of the difference between an opinion and a statement of fact in giving evidence. There is a certain amount of distrust of expert evidence which is due, no doubt, to a lack of appreciation of this difference by some expert witnesses as well as by the general public. But a professional man should not sink his dignity by accepting a fee to express an opinion in court without having satisfied himself that the facts submitted to him and examined by him warrant such opinion. As Dr. Cohen says: "Evidence should be given with a view to elucidate the truth and not to score points for or against either side."

A Mission Hall as a Common Lodging House.

Miss M. Barclay was fined £2 with £5 5*s.* costs by Mr. Chapman on April 26th for keeping a mission hall in Paradise-street, Rotherhithe, as a common lodging house. The facts had been gone into at a previous hearing but the case had not been decided owing to the appeal from a decision by another magistrate, Mr. Cluer, in a similar case not yet having been decided, and it had been understood that Miss Barclay would endeavour to prevent the circumstances constituting the alleged offence from recurring meanwhile. The defendant, a lady whose benevolent intentions are beyond dispute, urged in her own defence that the men admitted to the hall had nowhere to sleep and were tired; she also added that they were asked not to go to sleep and that there was no law to prevent men from going to sleep in a mission hall and that other gentlemen present in court no doubt sometimes fell asleep in church. This somewhat feminine line of argument did not prevail with Mr. Chapman, who pointed out to the defendant that he had to administer the law as it stood and that, in his opinion, she had brought herself within its provisions. He might have added that the law relating to common lodging houses exists for the benefit of the very class in whose physical welfare Miss Barclay is interested. In providing certain regulations for the sanitation of such places the law not only protects the community but increases the comfort as well as the safety of the individuals whose hard lot compels them to frequent the lodging house.

The Medical Man, the Coroner, and the Pathologist.

At an inquest held recently at Wandsworth, Mr. E. R. Badcock, medical officer to the local Poor-law authorities, gave evidence, the deceased having died after Mr. Badcock had ordered his admission to the infirmary but before he could be conveyed thither. In the course of his evidence Mr. Badcock protested against not having been afforded an opportunity of attending the post-mortem examination, which was made as usual by Dr. L. Freyberger. Mr. Troutbeck's reply to this complaint is thus reported in the *Daily Telegraph*: "It is quite useless of you making these silly protests. Continue your evidence." When the witness had stated his opinion as to the cause of death the coroner addressed him thus: "Why would you not certify as to death? These were respectable people and you had the history of the case I object very much to having these inquests forced upon me" If Mr Troutbeck does not find that he enjoys the coöperation and the goodwill of the medical practitioners in his district he has only himself to thank , in any case, however, the medical man has to certify upon his own responsibility as to the cause of death, whether the deceased s relatives are respectable or not, and is perfectly right not to do so if his attendance upon the deceased has not been such as to enable him to certify with confidence Mr Badcock complained that he was not enabled to be present at the post mortem examination in order that he might observe for himself whether such opinion as he had formed was justified If, however, he had attended the deceased "at his death or during his last illness ' he was the proper person not merely to be present at the post mortem examination but actually to make it himself according to the 21st section of the Coroners Act, 1887 That he had so attended the deceased Mr Troutbeck would, presumably, not dispute, after having expressed the opinion that he should have given a certificate as to the cause of death

The Forensic Position of Deaf mutes

Dr W Wynn Westcott lately had a deaf mute woman before him in his coroner's court who had overlaid her baby The coroner s officer gave most of the evidence and the verdict was eventually returned of ' Accidental death ' The law recognises two varieties of muteness A man upon arraignment may be "mute of malice, ' wilfully refusing to plead at all or he may be mute not of malice but from 'the visitation of God" Should occasion arise this latter condition *et surdus et mutus a nativitate* is a presumption in law of idiocy as coming under the heading *dementia naturalis* Some difficulty arises when a deaf mute witness has to be examined , he cannot hear the terms of the oath under which he is sworn and his testimony must be either written down by himself or transmitted through an interpreter as was decided in a case tried in 1827 Formerly previously to ' the schoolmaster being abroad, illiterate deaf mutes accused of malingering in court were subjected to great hardships , thus in 1734 John Durant was tortured with the thumb screw in order to force him to plead, he was probably deaf and certainly illiterate A legal decision affirmed that a deaf mute might marry (1 K & J 4) In 1876 a deaf mute was found guilty but unable to appreciate the forensic proceedings , he was therefore detained as a non sane person during Her Majesty s pleasure In 1900, at the Salisbury autumn assizes a deaf mute was allowed to plead in writing At the Central Criminal Court in 1897 a man who had cut his own throat after committing a murder was upon arraignment only able to whisper "not, owing to the damaged state of his larynx , he subsequently received a capital sentence In olden times after being thrice warned *prisone* or *peine fort et dure* was the lot of one suspected of inconvenient taciturnity muteness of malice , the reason for the assumption of dumbness was not far to seek, for one who did not plead at all could not be convicted nor could his lands be forfeited , thus did men lose their lives to save their estates for their families

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In 76 of the largest English towns 8434 births and 4954 deaths were registered during the week ending April 29th The annual rate of mortality in these towns, which had been 15 7, 16 6, and 15 6 per 1000 in the three preceding weeks rose again to 16 5 per 1000 last week In London the death rate was 15 9 per 1000, while it averaged 16 8 per 1000 in the 75 other large towns The lowest death rates in these towns were 8 1 in Hornsey 8 2 in King s Norton, 8 3 in Wallasey, 8 7 in Bournemouth 8 9 in East Ham, and 9 6 in Northampton, while the highest rates were 22 1 in St Helens, 22 8 in Stockport 22 9 in Wigan 24 2 in Sunderland 25 4 in Merthyr Tydfil, 25 8 in Newport (Mon), and 27 0 in Middlesbrough The 4954 deaths in these towns last week included 460 which were referred to the principal infectious diseases, against 430, 553, and 453 in the three preceding weeks , of these 460 deaths, 203 resulted from measles, 122 from whooping cough, 42 from diphtheria, 40 from diarrhœa, 32 from scarlet fever, 20 from "fever" (principally enteric), and one from small pox No death from any of these diseases was registered last week in Hornsey, Leyton, Bournemouth Great Yarmouth, Norwich, Plymouth, Wolverhampton, Grimsby, Wallasey, Bootle, Bury, or Rochdale, while they caused the highest death-rates in West Bromwich, Coventry, St Helens, Oldham, Sheffield and Merthyr Tydfil The greatest proportional mortality from measles occurred in West Bromwich, Coventry, St Helens, Wigan Warrington, Sheffield, Sunderland Newport (Mon), and Merthyr Tydfil, and from whooping cough in Willesden, Tottenham, and West Ham The mortality from each of the other principal infectious diseases showed no marked excess in any of the large towns One fatal case of small pox occurred in London, but none in any other of the 76 towns The Metropolitan Asylums Hospitals contained 16 small pox patients at the end of last week, against 21, 15 and 17 at the end of the three preceding weeks , four new cases were admitted during the week, against four, none and six in the three preceding weeks The number of scarlet fever cases remaining under treatment in these hospitals and in the London Fever Hospital which had been 2086, 2133 and 2128 at the end of the three preceding weeks, had risen again to 2182 at the end of last week , 255 new cases were admitted during the week, against 292 290 and 253 in the three preceding weeks The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 308 304 and 272 in the three preceding weeks increased to 306 last week, and were 82 in excess of the number in the corresponding period of last year The causes of 72 or 1 5 per cent , of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Portsmouth Bristol, Leeds, Newcastle on Tyne, Cardiff and in 46 other smaller towns , while the largest proportions of uncertified deaths were registered in Reading, Norwich, Birmingham Liverpool, St Helens, Warrington, Sheffield, Sunderland, South Shields, and Gateshead

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 16 6, 18 0, and 17 8 per 1000 in the three preceding weeks, rose again to 18 8 per 1000 during the week ending April 29th and was 2 3 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 12 8 in Leith and 15 9 in Dundee to 20 8 in Greenock and 21 1 in Glasgow The 632 deaths in these towns included 27 which were referred to whooping cough 21 to measles, eight to diarrhœa, and one each to scarlet fever, diphtheria and enteric fever, but none to small pox In all 59 deaths resulted from these principal infectious diseases last week, against 69 in each of the two preceding weeks These 59 deaths were equal to an annual rate of 1 8 per 1000, which was 0 3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 28 36, and 23 in the three preceding weeks rose again last week to 27 of which 18 occurred in Glasgow, four in Paisley two in Edinburgh, and two in Dundee The deaths from measles which had been 13, 17, and 23 in the three preceding weeks, declined to 21 last week and included 15 in Glasgow and five in Edinburgh The fatal cases of diarrhœa, which had been 20, nine and 12 in the three preceding weeks, decreased again last week to eight, of which six were recorded in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 119 121, and 126 in the three preceding weeks, declined again to 121 last week and were equal to the number in the corresponding period of last year The causes of 18, or nearly 3 per cent , of the deaths registered in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 25 5 21 6, and 23 4 per 1000 in the three preceding weeks, declined again to 21 9 per 1000 during the week ending April 29th During the past four weeks the death rate has averaged 23 1 per 1000, the rates during the same period being 15 7 in London and 16 0 in Edinburgh The 159 deaths of persons belonging to Dublin registered during the week under notice were 11 below the number in the preceding week and included eight which were referred to the principal infectious diseases, against five, eight, and 12 in the three preceding weeks; of these, three resulted from diarrhœa, two from measles, two from "fever," and one from whooping-cough, but not any from small-pox, from scarlet fever, or from diphtheria. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 1·4 in Edinburgh. The fatal cases of diarrhœa, which had been two, none, and three in the three preceding weeks, were again three last week. The deaths from measles, which had been four in each of the two preceding weeks, declined last week to two. The 159 deaths in Dublin last week included 23 of children under one year of age and 48 of persons aged 60 years and upwards; the deaths of infants showed a considerable decline, while those of elderly persons were equal to the number in the preceding week. Four inquest cases and three deaths from violence were recorded; and 63, or nearly two-fifths, of the deaths occurred in public institutions. The causes of ten, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments are notified:—Fleet Surgeons: W. W. Pryn to the *Goliath*, R. H. Nicholson to Portsmouth Dockyard, J. H. Whelan to the *Canopus*, W. Bett to Greenwich Hospital School and R.N. College; and J. H. Acheson to the *Russell*. Staff Surgeons: H. W. Finlayson to the *St. George*; H. N. Stephens to the *Topaze;* and L. Kilroy to the *Wildfire*. Surgeons: S. Roach to the *Cambridge* and H. P. Turnbull to Haslar Hospital.

Army Medical Staff.

Surgeon-General Sir E. Townsend, K.C.B., C.M.G., is placed on retired pay (dated April 22nd, 1905). Colonel R. H. Quill, from the Royal Army Medical Corps, to be Surgeon-General, vice Sir E. Townsend, K.C.B., C.M.G. (dated April 22nd, 1905).

Royal Army Medical Corps.

Lieutenant-Colonel O. E. P. Lloyd, V.C., to be Colonel, vice R. H. Quill, promoted (dated April 22nd, 1905). Captain O. Challis resigns his commission (dated May 3rd, 1905).

Major J. C. Connor joins at Portsmouth. Captain J. M. Sloan, D.S.O., assumes the duties of Recruiting Medical Officer, Glasgow, during the absence on leave of Lieutenant-Colonel W. V. Lane from May 1st to June 30th. Captain A. H. O. Young takes over charge of staff and departments of the Belfast Garrison.

Indian Medical Service.

The King has approved of the following promotions among officers of the Indian Medical Service made by the Government of India:—Captains to be Majors (dated Jan. 30th, 1905): *Bengal Establishment:* Charles Milne, Vivian Godfrey Drake-Brockman, William Young, John Joseph Bourke, Bernard Robert Chatterton, Cedric Barkley Prall, Charles Edward Williams, John Norman MacLeod, Walter Holland Ogilvie, Thomas Alfred Ollivant Langston, Richard Heard, Edgar Rowe Parry, Walter Hood Orr, and Paxton St. Clair More. *Madras Establishment:* George Bidie. Lieutenants to be Captains (dated Jan. 29th, 1905): Alfred Ernest John Lister, Thomas Samuel Beauchamp Williams, Samuel Herbert Lee Abbott, Alexander William Greig, Richard Ernest Lloyd, John Edmund Clements, Hugh Barkley Steen, Ernest Bisset, Richard James Bradley, James Woods, Alexander William Overbeck-Wright, David Munro, Thomas William Harley, John William McCoy, Roger Lionel Hagger, Robert Markham Carter, Roger Durrant Willcocks, Thomas George Ferguson Paterson, Dodington George Richard Shurton Baker, Jasper Robert Joly Tyrell, Dewan Ganpat Rai, Robert Macpherson Barron, William Reith John Scroggie, Lewis Patrick Farrell, Thomas Henry Gloster, Herbert Henry George Knapp, James Henry Horton, D.S.O., and William Adolphus Justice.

Royal Army Medical Corps (Militia).

Dublin District Company: Captain (Honorary Captain in the Army) J. Davies resigns his commission (dated April 1st, 1905).

Volunteer Corps.

Royal Garrison Artillery (Volunteers): The Highland: Surgeon-Lieutenant G. Wilson to be Surgeon-Captain (dated April 22nd, 1905).

Royal Engineers (Volunteers): 1st London: Surgeon-Lieutenant E. O. Roberts to be Surgeon-Captain (dated March 28th, 1905).

Rifle: 4th (Hunts) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Captain W. F. Fisher resigns his commission (dated April 22nd, 1905). 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant-Colonel G. P. Alexander resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated April 22nd, 1905). 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Surgeon-Lieutenant E. O. Stack to be Surgeon-Captain (dated April 22nd, 1905).

Army Medical Reserve of Officers.

Surgeon-Major R. T. C. Robertson to be Surgeon-Lieutenant-Colonel (dated April 11th, 1905).

Army Reform.

From intimations which have appeared in the daily press it would appear that Mr. Arnold-Forster and the military members of the Army Council are not at one in regard to the new army scheme put forward by the War Minister. Notwithstanding the various explanations which have been given in the House of Commons regarding its object and character, but rather in consequence thereof, it cannot be said that anybody knows exactly "where we are" in this matter. It seems clear that Mr. Arnold-Forster has not succeeded in carrying conviction to the minds of all those whom he sought to convince that he has produced a sound, well-balanced, and workable scheme. It is certainly incomplete from a sanitary and medical point of view to meet all the requirements of war and whether the scheme as a whole will prove successful in attracting the requisite number and quality of recruits into the army and in providing a sufficient army reserve are points which have still to be settled by the tests of trial and experience.

The Field Ambulance.

A description of the new unit, "The Field Ambulance" has recently been published by the War Office. It takes the place of the bearer company and the field hospital and is under the command of a lieutenant-colonel. The total *personnel* consists of 252 of all ranks; these are divided into (1) a bearer, (2) a tent, and (3) a transport division. The bearer division consists of a *personnel* of 129, of which 117 are privates; 90 of these may be "specially enlisted men." The tent division has accommodation for 150 patients; three of the officers may be civilian surgeons. In the transport division no less than 60 of the Army Service Corps are employed but without an officer from that corps. Each field ambulance is attached to a brigade. There is also one for the corps troops. In a cavalry brigade there is only accommodation for a field ambulance equipped for 50 patients and the *personnel* is accordingly reduced to 120.

The Volunteer Ambulance School of Instruction.

The annual banquet of the school will be held at the Trocadéro Restaurant, Piccadilly-circus, London, W., on Thursday, May 18th, at 7.45 P.M. The chair will be taken by the senior medical officer, Surgeon-Colonel P. B. Giles, V.D. The string band of the 1st Cadet Battalion of the Royal Fusiliers will perform a selection of music during the evening. Past and present members of the school can obtain tickets by applying to the mess president, Surgeon-Captain E. M. Callender, 47, Connaught-square, W.

The Water at Tregantle Fort, Plymouth.

It is notified in Plymouth Coast Defence orders that "troops are prohibited from drinking water or gathering crabs for eating purposes from the stream running past the firing points on B range at Tregantle, the water being polluted and unfit for use."

The War in the Far East.

The news from the theatre of war as to actual operations is extremely meagre and such being the case the crop of rumours is proportionately heavy. It is necessarily a time of tension and anxiety, for the importance of the result of the coming naval engagement cannot be exaggerated. Everything may be said to depend upon it. But no one can guess, and still less foretell, what are likely to be the nature and the extent of the naval operations nor where they will take place We know but little about the position of the Russian fleet at the present time and cannot safely conjecture where that of the Japanese lies hidden. A little insight into the condition of the Russian land forces may be obtained from an order recently issued by General Linievitch forbidding the destruction of stores without the express permission of superior authority. It appears to have come to the Russian general's knowledge that commissariat stores had been destroyed at a time when the troops were in urgent need of them and when no food rations and forage had been issued for several days

In consequence of the recent decision to accept the services of medical men with degrees from foreign universities for service in the Far East, the Russian local papers say that already applications are coming to the Bessarabia and Kherson district councils from both male and female medical practitioners who have graduated in Switzerland, France, and Germany

A travelling correspondent of THE LANCET, who was present at the retreat from Mukden and who reached Harbin towards the end of March, has written us an interesting letter. He found that in spite of his knowledge of the Russian language and of the scarcity of medical men, which made any medical assistance valuable, his English origin caused him to be always an object of suspicion He says that he had great difficulty in getting to Mukden, though German and French medical men were allowed to visit the hospitals. Of Harbin he says that on March 28th the city contained 70 000 wounded It was one large hospital, no less than 27 Red Cross hospitals were trying to cope with the terrible situation, while their efforts were minimised by the fact that the Russian army officers are at loggerheads with the Red Cross organisation

Correspondence.

"Audi alteram partem."

SECURITY OF TENURE FOR MEDICAL OFFICERS OF HEALTH.

To the Editors of THE LANCET

SIRS,—I was delighted to see in THE LANCET of April 29th a letter from Mr Herbert Jones on this vitally important question In my capacity as secretary for the North Western Branch of the Incorporated Society of Medical Officers of Health my attention was drawn about a month ago to a case of equally great hardship to those quoted in your annotation I do not think I am violating any confidence by giving you the particulars of it The case is that of Mr N Hannah, for no less than 30 years medical officer of health for the Abram urban district council, near Wigan, Lancs Mr Hannah served this council for half a lifetime without any complaint having been made as to the performance of his duties The district council concerned had been in the habit, we were informed, of making this appointment annually, on the re appointment becoming due this year it was made a condition that the officer appointed should reside within a mile radius *of the district council offices* Mr Hannah, who is in private practice and who is also medical officer of health for an adjoining district, found it impossible to comply with this condition and was accordingly passed over when the appointment was made The matter was reported by some member acquainted with the circumstances to the local branch of the Medical Officers of Health Society and a resolution was passed that the attention of the Local Government Board be drawn to this detrimental system of making annual appointments and particularly to the terms of advertisement for the appointment to which I have alluded The meeting at which this resolution was unanimously carried was one attended by medical officers of health for counties, county boroughs, municipal boroughs, and urban and rural districts, and I can assure you that the greatest possible sympathy was felt for Mr Hannah by the branch I have no doubt whatever that if your readers would take the trouble of putting you in possession of information relating to cases similar to this the objects of the Bill now before Parliament would be considerably advanced.

I am, Sirs, yours faithfully,

Stockport, April 29th, 1905 MEREDITH YOUNG, M.D. Edin.

GALL-STONES AND CANCER.

To the Editors of THE LANCET.

SIRS,—The interesting paper by Dr. G. R. Slade in THE LANCET of April 22nd, p 1059, and your annotation thereon are of so remarkable a character as to warrant some discussion In the main one can have no difficulty in agreeing cordially with Dr. Slade's conclusions—conclusions which have already been accepted by most writers upon the subject—to the effect that the association between gall stones and cancer is close and that gall stones are the determining cause of cancer of the gall bladder His final conclusion, that cholecystectomy should be performed whenever possible if any thickening of the gall-bladder be found at the time of operation, is one the value of which I have often urged In two papers published in the *British Medical Journal*, Vol I, 1903, p 186, and in THE LANCET of April 30th, 1904, p 1190, and in my work on ' Gall stones and their Surgical Treatment," I have pressed the claims of cholecystectomy in place of cholecystotomy in many cases Dr Slade indeed repeats some of the arguments used by me in those articles But although I agree with Dr Slade's conclusions, I cannot admit that his figures are anything but exceptional It is perfectly clear that the whole series of cases was of an unusual character 61 operations were performed with 17 deaths, a mortality of 27 8 per cent That alone shows the serious nature of the cases and I venture to assert that the conditions found on post mortem examination are as far from the average as is a mortality of 27 8 per cent from the average mortality of operations performed for gall stones and the complications caused by them

So far as concerns the frequency of cancer in association with gall stones, the evidence afforded by the statistics of the surgeons does not coincide with the experience of Dr Slade *Carcinoma of the gall bladder does not occur in* 18 per cent of operations and it certainly cannot be admitted that "over 50 per cent of all cases of gall stones end in malignant disease ' It is clear, I think, that the earlier stages of gall stone disease in which operation should be practised, so that these grave complications are avoided, is very sparsely represented in this series If malignant [illegible] gall bladders we [illegible] amination of such [illegible] should hear more of troubles subsequent to the performance of cholecystotomy when such conditions were present

I have performed cholecystectomy over 40 times In two of these cases the gall bladder was removed because it was clearly affected with malignant disease In 18 there was gross thickening of the walls of the gall bladder, in only one of these specimens was malignant disease found after careful examination So far as I know only two cases have been recorded of malignant disease of the gall bladder occurring in patients upon whom cholecystotomy had been performed Both these cases are mentioned on p 325 of my book on gall stones, they occurred in the practices of Mr R Lawford Knaggs and Mr A W Mayo Robson. When many surgeons can number their operations for gall stones by hundreds and a few by thousands, it seems reasonable to suppose that if malignant disease occurred after cholecystotomy we should hear of it occasionally I submit, therefore, that the gall bladders, thickened by chronic inflammation, which are removed by operation do not show evidence of malignancy on investigation in anything more than a very small proportion of cases and that such gall-bladders when drained by the operation of cholecystotomy do not suffer from malignancy subsequently except in the rarest circumstances It is, I am fully aware, often difficult to reconcile post mortem experience with the experience of the operation table, especially when the material in each case is liable to considerable variations The number of cases in each class in Dr Slade's series is so small that it is quite possible that a further investigation will alter the results considerably. So far as concerns the remarks under "Surgical Aspects," I do not hesitate to say that the figures given are opposed to the published experience of all surgeons whose cases are numbered in hundreds—Kehr, the Mayos, Mayo Robson, and to my own. Thus in 547 operations recorded by Dr. W. J. Mayo malignant disease was found 25 times, a percentage of rather less than five. In this series are ten cases of "exploration" only, the condition found being inoperable. In Kehr's statistics the malignant cases and the acute infective cases are grouped together; of these, there were 129 cases in a total of 1000. In 500 cases operated upon by Mayo Robson there were 49 cases of malignant disease. In my own experience malignant disease has been present in almost exactly 5 per cent. of the cases submitted to operation. And these statistics include not cases of malignant disease of the gall-bladder only but cases of malignant disease in the liver or the head of the pancreas or any part of the bile passages.

Though I cannot agree that Dr. Slade's experience represents, even approximately, the average, I cannot but feel that his investigation is one of great worth and that his support of the view I have long held of the necessity for the more frequent performance of cholecystectomy is most valuable. I think his figures are exceptional but I am sure his conclusions are sound.

I am, Sirs, yours faithfully,
Park-square, Leeds, April 27th, 1905. B. G. A. MOYNIHAN.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

To the Editors of THE LANCET.

SIRS,—In view of the epidemics of cerebro-spinal meningitis prevailing at present in New York and elsewhere it may be of interest to report three cases which occurred 12 months ago in my practice in the country near Banbridge, co. Down, and which I regarded at the time as cerebro-spinal meningitis. All three patients belonged to the same family and lived in the same house.

1. The patient was a girl, aged nine years. The mother told me that she had been ill for five days with headache and pains in the back, but she had not been in bed before I saw her. She cried frequently, was dull and listless and slow to answer questions. She had marked photophobia. The temperature was 102° F. and the pulse was 100. Examination of the chest and abdomen revealed nothing abnormal except a slight petechial rash over the skin; the spots were small and distinctly hæmorrhagic and quite unlike any of the ordinary exanthemata. The tongue was slightly coated; the throat was inflamed; there was no diarrnœa. She was placed in bed in a darkened room with ice applied to her head. Four hours later I received a telegram saying that she was dying, and so it proved. She had had a series of very severe convulsions, the temperature ran up to 106·4°, and, in fact, she died half an hour after I arrived. I was painfully surprised at this abrupt termination but I did not suspect then that the case was anything but meningitis of one of the usual types.

2. Nine days later in the same house I saw a boy, aged 14 years, a brother of the first patient. He had been ill for two days and his symptoms were almost identical with those of his sister when I first saw her. Continuous pain, mental torpor, photophobia, and petechial rash were all present. He also had an inflamed throat and the temperature was 102° F. The following day he was worse; there was well-marked retraction of the neck and spine and Kernig's sign was present; later there were spasms of the muscles but no convulsions, also hyperæsthesia over the spine, with increasing pain and difficulty in extending the legs. It seemed a typical case of cerebro-spinal meningitis and to confirm this view I proceeded to perform lumbar puncture to have the cerebro-spinal fluid examined for the diplococcus. In this, however, I unfortunately failed, for on inserting the needle, owing to the violent struggles of the boy and the sympathy of his father, I was compelled to desist, to my lasting regret. This was on the fifth day of his illness; about the seventh the symptoms began gradually to subside and he was convalescent in a fortnight. He was placed on no special treatment beyond rest and isolation in a darkened room, ice-cap, bromides, and antipyrin. The rash gradually disappeared during recovery after the other symptoms subsided.

3. During the convalescence of the last patient his sister, a girl aged 18 years, took ill in exactly the same way. She developed all the symptoms enumerated above, including the petechial rash, but they were less severe and convalescence set in about the tenth day. Both these last two cases were quite well within three weeks and no other similar cases occurred in the house or neighbourhood.

Without having bacteriological proof I would like to know whether the above history and symptoms should justify the diagnosis of cerebro-spinal meningitis in the absence of an epidemic and, if so, in what way might such an occurrence be explained. There was, of course, the epidemic in Dublin five years ago which I was fortunate enough to witness but since then I had neither seen nor heard of any cases in Ireland until these three occurred in such a curious, and to me inexplicable, manner.—I am, Sirs, yours faithfully,

J. HOPE REFORD, M.D. R.U.I.
Crossmyloof, Glasgow, April 20th, 1905.

To the Editors of THE LANCET.

SIRS,—The leading article on Epidemic Cerebro-Spinal Meningitis in THE LANCET of April 15th has drawn the attention of the medical profession in England to this disease; at the same time the English-speaking community on the continent has read of it *ad nauseam* in the columns of the *New York Herald*. It would appear that all which has been discovered in connexion with this disease should be matter of common knowledge, at any rate to our profession. Yet, as your article says, "our knowledge of the conditions leading to the epidemic spread of cerebro-spinal fever is of the scantiest." Some four years ago when in Egypt I read an interesting paper by the late Major Hill-Smith, R.A.M.C., of the Egyptian Army Medical Corps. It was published, I believe, in the annual report of the principal medical officer of the Egyptian army in 1899 or 1900. As I have never seen this paper referred to I presume that it did not attract any attention, yet at a time when once more so much is written of epidemic cerebro-spinal meningitis I may be excused for quoting from memory from a paper which contained an observation of possible importance. When after the battle of Omdurman the Egyptian army took possession of the town an epidemic disease soon arose among the troops quartered in the neighbourhood of the Mosque square. This disease was proved to be epidemic cerebro-spinal meningitis clinically and pathologically and, as far as the conditions obtaining at Omdurman allowed, bacteriologically. The disease first broke out among the companies occupying certain buildings which had been used previously by the Khalifa as stables for the horses of his cavalry and quarters for the men in charge of the horses. The case incidence was much the heaviest in this spot and spread in diminishing intensity from it, indicating, as Major Hill-Smith's map clearly showed, this as the original focus of the disease. Following up this clue it was found on inquiry that a fatal form of horse sickness had been endemic in these buildings and that two years previously it had been so severe and so fatal that the stables had been abandoned and not used until their occupation by the troops of the Egyptian army.

These facts seem to warrant at least the suggestion that the horse sickness and the outbreak of cerebro-spinal meningitis had some close connexion, a suggestion to which subsequent observations of Major Hill-Smith further up the country lent additional support, if I remember his paper correctly, but at this distance of time I cannot be sure of these last observations. With regard to the facts about the epidemic at Omdurman my memory is, I think, accurate, as I spent some six months in Omdurman shortly after reading this paper and the impression of it was increased by the local associations. Where, as the writer of your article admits, our knowledge is so scanty any suggestion based on accurate observation is worth attention and so I venture to recall to your notice the late Major Hill-Smith's paper.

I am, Sirs, yours faithfully,
Florence, Italy, April 19th, 1905. EDWARD A. GATES.

PEOPLE'S SANATORIUMS AND PRIVATE SANATORIUMS.

To the Editors of THE LANCET.

SIRS,—I have read with interest the first part of your Commissioner's report written from "Nordrach." There cannot be too much enlightenment on the methods and practice of the different sanatoriums, even of one so familiar to most of us interested in the treatment of tuberculosis as Nordrach Colonie.

May I, with your permission, make one or two remarks? I do not hold a brief for Jones's Homes at Sandgate, nor do I approve of its arrangements if they are carried on in the style described by *Truth* from time to time. It seems to me, however, scarcely consistent with fairness to take the private sanatorium of Dr. Walther at Nordrach Colonie as being the one referred to in the circular as "the open-air cure practised at Nordrach, Leysin, &c.," as evidently (taking into consideration the cost of treatment) the *people's sanatoriums* are the places referred to. One of these existed at Nordrach (village) where the patients (sent by the State insurance societies) occupied the ordinary village houses and when passing through a few years since I saw dozens of these patients walking about through the streets, in and out of the shops, just as they are described as doing at Sandgate. At another village in the Black Forest, Schömberg, where Herr Römpler's and another private sanatorium are situated, there was also a Volk's Sanatorium on the boarding-out system. One or two curiously decorated structures were pointed out to me as galleries or verandahs which looked out on a narrow and shut-in street.

If your Commissioner would describe some of these Volk's
›w the patients spend their
and the character of the
eaders would be extremely
vhen in Germany was that
Falkenstein, Hohenhoneff,
and Nordrach Colonie are comparatively easy to see but that the less known institutions were not always easy to obtain information about. As an instance, I was unblushingly informed at one sanatorium that another (not 20 miles distant) did not exist. Dr. F. Rufenacht Walters gives a list of people's sanatoriums in his "Sanatoria for Consumptives," but several names might be added now to that in the 1901 edition.

Your Commissioner impresses one as taking rather a different view of the infectivity of phthisis from that expressed in your excellent leading article on Public Health in the Transvaal, where you emphasise the fact that in pulmonary phthisis infection is only possible when certain simple precautions are not observed.

It has been repeatedly pointed out that the presence of sanatoriums in the villages had a beneficial educational effect—e.g., Falkenstein and Göbersdorf. About eight years ago in this city (Belfast) the fear of the infectivity of phthisis was so rampant that great difficulty was experienced in obtaining a new site for the Consumption Hospital. Now this dread has so far subsided that applications are constantly being made for permission to build villa residences inside the hospital grounds.

I am, Sirs, yours faithfully,
F. HOWARD SINCLAIR,
Visiting Physician, Forster Green Hospital, Belfast.
Belfast, April 30th, 1905.

SHOCK AND COLLAPSE.

To the Editors of THE LANCET.

SIRS,—I quite agree with Mr. P. Lockhart Mummery that arguments should be based on experimental evidence, but these arguments must satisfy the ordinary laws of reasoning. I based my arguments on the elementary fact which has been overlooked by Mr. Mummery—namely, that fluid transmits pressure equally in all directions. Surely this requires no further experimental proof. Mr. Mummery apparently thinks that increased atmospheric pressure tends to drive the blood from the peripheral to the deeper vessels but that this does not occur in health because the vaso-motor centre compensates for it by altering the calibre of the vessels. (Has Mr. Mummery any experimental proof of these views?) Are we to understand that the vaso-motor centre can keep open vessels which are subjected to an increased pressure of, say, two atmospheres? If so, by what mechanism does it *do so?* I pointed out in my former letter that increased atmospheric pressure could not affect the distribution of blood in the vessels because it was transmitted to all parts of the circulation equally. If it cannot alter the distribution, how can it alter the blood pressure? If the absolute pressure of the blood be x and the atmospheric pressure be y, the blood pressure as determined by instruments is $x-y$. If we increase y we increase x by the same amount according to the ordinary laws of hydrostatics and the blood pressure remains $x-y$. As to Crile's experiments I have not been able to refer to his book and must therefore rely on the short abstract given in the second lecture on p. 782. These experiments consisted in placing dogs in a condition of shock in tubes and then raising the air pressure in the tubes. It is not clear from the description whether the animal was completely inserted in the tube or whether it was only partially so inserted, but from the account given I concluded that part of the animal was outside the tube, because of the fact that the blood pressure was apparently recorded and it is not easy to see how this could be done if the whole animal was in the tube. I am confirmed in this view by the statement that, arguing from these experiments, "Crile attempted to treat human beings *in the same way.*" A description follows of the pneumatic suit in which the head and thorax are left outside. These experiments, then, refer to *localised* pressure only and I do not see how they support the hypothesis that *general* increase of atmospheric pressure will cause a rise of blood pressure.

Mr. Mummery says that in health increased abdominal pressure does not produce any appreciable alteration in the blood pressure because the vaso-motor centre is able to compensate for it. No doubt this is true within limits but is there no increase of blood pressure during forcible abdominal compression such as occurs in straining or during a vigorous muscular effort? It is obvious that when the abdominal vessels are dilated and the blood pressure is low the same amount of pressure will produce a larger effect than under normal conditions.

I am, Sirs, yours faithfully,
CHARLES POWELL WHITE.
St. Thomas's Hospital, S.E., May 2nd, 1905.

"THE KING'S CORONER."

To the Editors of THE LANCET.

SIRS,—*Your reviewer of the above book says:—*

> (1) The mere citation of the names of cases might well have been supplemented by more or less copious extracts from them upon any points likely to occur in practice. There would seem to us to be room, therefore, for a carefully compiled work of this class by a sound lawyer, with (2) perhaps chapters not only on such subjects as the law of evidence but a few practical hints on the actual eliciting of it from witnesses and upon such cross examination as the coroner is justified in administering in order to sift their stories where he has no legal assistance from interested parties.

Concerning (1), I may say that I have been engaged for a considerable time upon the work suggested, so that "Mr. Henslowe Wellington will amplify his work in this direction" as proposed by your reviewer. Concerning (2), "the law of evidence" and "the actual eliciting of it from witnesses and such cross-examination as the coroner is justified in administering" can only be acquired by attending the Central Criminal and other High Courts and carefully studying the judge, counsel, and witnesses, as is the daily routine of, Yours faithfully,
R. HENSLOWE WELLINGTON,
Barrister-at-Law and Deputy Coroner.
Temple, April 29th, 1905.

⁂ We understand Mr. Wellington to mean that he had intended to do what our reviewer recommended him to do—an example of what the American psychologist called "the simultaneous consaltation of higher intelligences."—ED. L.

ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND.

To the Editors of THE LANCET.

SIRS,—It is the intention of the above association to present a petition to the Royal College of Surgeons of Edinburgh at the forthcoming fourth centenary praying that the title of "Licentiate" may be altered to "Member." Let me urge upon those holding diplomas of the Scottish corporations to join the association forthwith in order that we may voice the wishes of all the Licentiates. It is very important that this object should be pushed forward as rapidly as possible. Our honorary secretary, Dr. David Walsh, 18A, Hanover-street, W., will be glad to receive the names of those interested in this urgent and far-reaching movement and wishing to become members.

I am, Sirs, yours faithfully,
CLAUDE ST. AUBYN-FARRER, President.
London, W., May 1st, 1905.

THE PETITION OF THE LICENTIATES OF THE SOCIETY OF APOTHECARIES TO THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,– [illegible] ›ly to numerous
inquiries [illegible] *ally* affected by
the non- [illegible] be greater than
is generally [illegible] of the Medical

Directory for 1905 shows that 1571 persons now practising hold the diploma in medicine, surgery, and midwifery of the Society and of these 809 (nearly 51 per cent.) have taken no additional qualification. It has been suggested by some correspondents that the Society should seek the designation of Faculty of Physicians and Surgeons of London. Such persons have not studied the history of the London medical corporations or they would know that the charter of the College of Physicians was granted to "the President and College, or Commonality, of the Faculty of Physic of London." The body of the Licentiates of the Society has no desire to usurp the titles of other corporations, and that which is asked for in the petition (Lic. Med., Surg., and Midwifery of the Society of Apothecaries) was carefully considered so as not to trespass on the rights of other bodies and at the same time to do a simple act of justice to a considerable number of practitioners. May I ask any Licentiates who have not sent their proxies for the signature of the petition to do so at once?

I am, Sirs, yours faithfully,
A. RIVERS-WILLSON,
Oxford, May 1st, 1905. Chairman of Petition Committee.

SCHOOL ATTENDANCE AND PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—I think the attention of your constituency should be drawn to the present irrational and intolerable methods of insuring attendance at elementary schools. In innumerable instances the attendance officer discharges his duties without exercising the slightest discretion, with the result that the poorer classes are often subjected to a petty tyranny of officialdom little better than that of certain notorious continental States, and, in addition, are subjected to real danger and suffering in the matter of health. The regulations seem to allow of only two alternatives: a child must attend school or the parent must provide a medical certificate. It is perfectly obvious that an unreasoning interpretation of this rule will often involve, to parents and children, much unnecessary trouble and pain; but what is more serious will often lead to very great risks to public health. Everyone knows that there are many cases of slight but troublesome illnesses, such as nasal catarrh, toothache, diarrhœa, and biliousness, where the parents are competent to judge that the child is unfit for school. In these cases the strain of school work or the exposure in school grounds may induce a serious illness and yet I can cite cases where the parents are continually being compelled to incur the expense of calling in a medical man on such trifling occasions as these.

I know many cases of delicate children with frequently recurring slight attacks of bronchial catarrh, sore-throat, &c., who need only the warmth and care of home for a day or two to restore them to ordinary health. Many of these parents cannot afford repeated fees for medical attendance. The result is that many children are at school who are *known* to be in an unfit state of health and the public health suffers in consequence. What is worse, I am able to prove that the want of discretion in the attendance officer often contributes to the spread of infectious diseases. Take my own district. By extreme measures we succeeded in eliminating nearly all cases of scarlet fever in this township. A fortnight ago two households were still infected. Hoping to confine the cases within these moderate limits, I felt justified in subjecting the houses to a prolonged isolation and requested the schoolmasters to allow no children to attend school from those houses until declared by me free from from infection. A fortnight ago the attendance officer insisted on the attendance of the children at school from one of the proscribed houses. A few days later a child of the family who had been from home during the actual visitation of the epidemic developed symptoms of scarlet fever, thus proving the house to be still infected. Within a week several scholars in the same school were also seized. This and similar cases are due to a blundering officialism which is far more eager to obtain the Government grant than to secure the best interests and real education of the children. I have even come across absurd cases where the inspector with the medical certificate before his eyes has insisted upon bandages being removed from an injured limb that his own petty officialism may be convinced. Certain inspectors insist that although the child is undoubtedly and seriously ill the medical certificate must be produced. It is scarcely credible but I have given a medical certificate for non-attendance, the certificate has been sent to the schoolmaster but has miscarried, and the parents have actually been summoned and fined in spite of a note from me explaining the circumstances!

What right has any attendance officer to assume that every parent is absolutely indifferent to his children's education? My experience is that parents are usually anxious to secure the best education for their children and are loth to see them surpassed by those of their neighbours. A law that was made for delinquents, I aver, is being employed to tyrannise over the well-disposed. In individual instances there are likely to be mistakes, but when the mistakes become the allowed and encouraged rule, especially when those mistakes result in universal annoyance and danger to the public health, it is indeed high time some determined effort were made to rectify them. To bring this grievance of the poorer classes home to our middle class, a friend spent a holiday in Preston with his daughter, a child of ten. The holiday did not happen to coincide with the stipulated school holiday. During the visit the child's life was made intolerable and her walks were almost entirely put a stop to by the unwarrantable interference with her liberty. Repeatedly she was pounced upon by attendance officers who treated her guardian, whether mother, father, or governess, with scant courtesy. Once she was caught alone when the official entered upon a tirade against "the criminal neglect of her father," who, by the way, is himself a public educationist.

Apart from the complaints I have made above this continual terror and tyranny must have an injurious effect upon the younger generation and is likely, unless remedied, to add one more element to the immense nervous stress that oppresses modern life and helps still further to add to the inmates of our crowded asylums. At least one grievous injustice should be immediately abolished. If school authorities compel the production of a medical certificate they should be also required to pay for it. I am inclined to believe some little condition of this nature will tend considerably to correct this blatant abuse.

I am, Sirs, yours faithfully,
A. E. W.

THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

COMMITTEE MEETING AT BERNE.

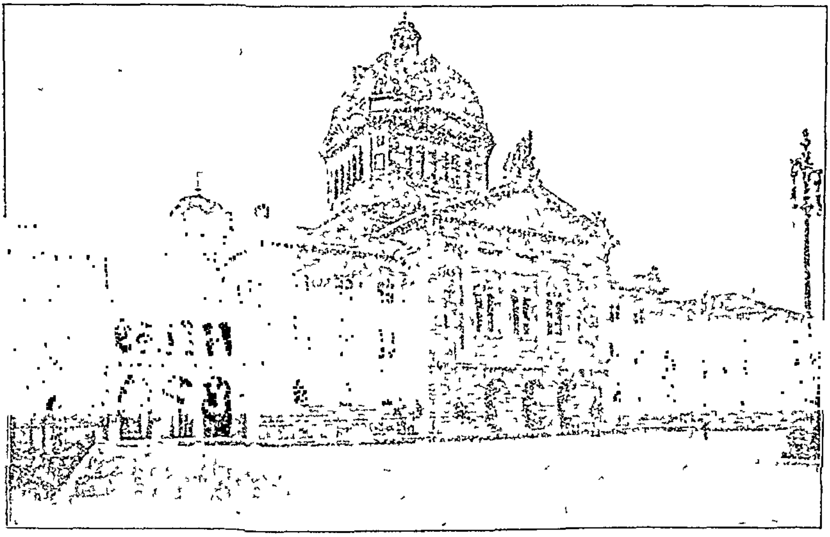
(FROM A SPECIAL CORRESPONDENT.)

Berne, May 1st.

THE committee of the International Association of the Medical Press met at Berne on April 27th and 28th. The Government of the Swiss Republic very graciously placed Committee Room No. 4 of the Houses of Parliament or Federal Palace at the disposal of the association. M. Ringier, the Chancellor of the Swiss Confederation, was present to receive the members of the committee and to welcome them in the name of the Swiss Republic. In a few well-chosen words he declared that he was profoundly touched by the honour conferred on his country when the representatives of the medical press decided to meet in the capital of Switzerland. But the other towns, in fact all Switzerland, would join in welcoming those who rendered great service to the science which did so much for the benefit of humanity at large.

It was at 9.30 A.M. that the committee met, and already on the previous day there had been much informal talk during the dinner and evening spent together at the Hôtel Bellevue. These conversations are almost as useful as, in some cases even more useful than, the formal meetings. It is by such intercourse that much information is obtained and plans are conceived and criticised. Dr. Carlos M. Cortezo, President of the International Association of the Medical Press, sent by telegraph his "affectionate salutations" and explained that, having just been appointed Minister of Public Instruction, he could not spare the time necessary to attend and to preside over the meeting of the committee; he therefore requested the Vice-President, Dr. Posner of Berlin, to occupy the chair in his stead. One of the first acts of the committee was to send a telegram of felicitations to His Excellency Dr. Cortezo. In his absence the Association of the Spanish Medical Press was represented by Dr. Larra y Cerezo who, it will be remembered, was general secretary of the International Congress of the Medical Press held at Madrid in

1903. Dr. Posner represented the Association of the Medical Press in the German language; this comprises the whole of the German Empire and the German-speaking portions of the Austrian Empire. The Association of the French Medical Press deputed the general secretary of the International Association, Dr. R. Blondel, and Dr. T. Amédée Dolčris. The Association of the Belgium Medical Press sent Dr. Victor Pechère, who is treasurer and assistant secretary of the International Association. The Association of the Portuguese Medical Press was represented by the general secretary of the forthcoming Fifteenth International Congress of Medicine, Dr. Miguel Bombarda. The Association of the Italian Medical Press was represented by Dr. L. M. Bossi of Genoa and the Association of the British Medical Press by Mr. Adolphe Smith. There is *as yet no* Association of the Medical Press of Switzerland and only two important medical papers are published in that country; [illegible] man language. [illegible], with the other [illegible] *für Schweizer Aerzte* was present as a Swiss representative. Early in the sitting, the chairman, Dr. POSNER, welcomed the presence of Dr. Jaquet and hoped that he would always attend as the medical press of Switzerland was a credit to the country.



The Federal Palace Berne, where the Committee of the International Association of the Medical Press held its meetings.

The business opened with the report of the general secretary, Dr. BLONDEL, who first explained that the last meeting of the committee was held in September, 1903, at Brussels, immediately after the International Congress of Hygiene On that occasion, Great Britain was represented by two delegates, France by two, and Portugal, Norway, and Belgium each by one delegate. It was then decided that nations could send substitutes for the committee-men elected at the last congress and also that the vote of the committee should not be by nationality, but as the last committee meeting was not well attended that these questions might be again taken into consideration At that time the question of subscriptions could not be discussed because the treasurer was not present. Dr. Blondel explained how the committee had been invited to hold its next meeting at Salsomaggiore in Italy, but that some of the members of the committee meeting at Brussels expressed doubts as to the wisdom of accepting such an invitation Dr. Blondel, after travelling all the way to Milan to ascertain full details, found that the invitation had been made by irresponsible persons who had promised more than they could perform and the project fell through. The question as to how far the committee was justified in accepting invitations and hospitality involved matters of principle which would have to be discussed. Ultimately and on the initiative of Dr. Cortezo and Dr. Posner it was decided to meet at Berne. From Norway and Denmark letters of excuse based on the great length of the journey to Berne had been received and thus these nations could not send delegates. No answer had come from America and an unfortunate misunderstanding had arisen with Russia. The Russian delegate to the Paris Congress had telegraphed from Trouville that he was unable to attend. Thereupon another medical man presenting a document in Russian which no one could read had applied and had been welcomed at the Paris Congress. It appeared, however, that he did not represent the Russian medical press at all but a paper published in the Baltic provinces and in German. Many apologies for the error had been made but the Russian medical journalists seemed very much aggrieved by this mistake. In conclusion, Dr. Blondel pointed out that during the greater part of the last ten years the idea of an international association of the medical press had existed only on paper Now, however, they were in a position to proceed from theory to action. It had been at first agreed that all existing national associations of the medical press could become members of the international association though now it might be necessary to be somewhat more careful But the first necessity was to acquire a decided influence and as a small step in this direction it would be proposed to publish .. [illegible] An attempt had [illegible] of journals to me— [illegible] succeeded, nor had it been possible as yet to obtain special railway privileges for members of the association.

After an expression of thanks to Dr. Blondel for his report the question as to how the committee should vote was taken first.

Mr. ADOLPHE SMITH explained that though he was the author of the proposal for a proportionate vote by nationality at the congresses or general meetings of the entire association he thought that the committee was purely an executive body. It was not its business nor had it the power to alter the constitution or policy of the International Association. Its only purpose was to carry into practice what had been agreed upon at the general meetings. In such purely practical matters only those who knew the facts could decide and only those actually present could assume the responsibility of such decisions. At Madrid and at Brussels the committee had voted by a show of hands.

After some brief observations by Dr. BOSSI, Dr. PECHÈRE, and Dr. BOMBARDA it was unanimously decided to adhere to these precedents. It was also stipulated that this matter having now been discussed at Madrid, Brussels, and Berne, it should not be raised again at the next meeting.

Dr. PECHÈRE (Belgium) inquired if a member of the committee could represent two nationalities. For instance, if his neighbours of the Dutch medical press had asked him to represent them, could he have accepted such a mission? In answer it was pointed out that such a contingency was not provided for by the rules and the committee had no authority to alter the rules.

Dr. BLONDEL explained that in striving to group the medical press it was essential to facilitate the meetings of its representatives. The cost of bringing the members of the committee together from all parts of Europe was very great and the question was whether it would be right to profit by offers made "out of respect for the press." There were wealthy health resorts which would like them to meet there. They had such constant and intimate relations with the railway companies that they could more easily obtain railway passes.

A very lengthy discussion ensued. Dr. PECHÈRE pointed out that in Belgium "journeys of medical study" were organised and the reduction in railway fares and the hospitality offered to the medical students who on these occasions visited health stations had never been subject to any unfavourable interpretation. But it would be necessary to go to different places and countries and not to show any sort of favouritism.

Dr. POSNER stated that German medical associations did not consider themselves in any way compromised because they had accepted hospitality at Carlsbad.

Dr. BOMBARDA considered that they could not be too jealous of their reputation. They were certainly justified in receiving railway passes but he had doubts about accepting *the hospitality of health resorts. It was not what they did* but what others might suspect them of doing.

Dr. BOSSI thought that there was much exaggeration in what had been said, though he fully understood the delicacy of the situation. One thing, however, was perfectly certain. They would never go to any place if expected to write about it and to praise its resources.

Mr. ADOLPHE SMITH said that in principle there could be no doubt that they should be absolutely independent and it would be best to accept nothing whatsoever. As for moral influence the most obvious proof of strength would be the fact that each national association was able to pay the cost of sending its representatives to the meetings of the committee. A few persons meeting together at the expense of their own societies would mean more and be more influential than a larger number whose presence had been facilitated by some outside help. On the other hand, it might be necessary in the beginning and pending such time as the national associations were rich enough to defray the entire cost of their delegates to seek some facilities, such as a reduction in railway fares, so that the cost of meeting might be less burdensome.

An animated discussion then ensued in the course of which it was urged that the hospitality of a State, a municipality, or a railway might be accepted but not that of an industrial society owning mineral waters and such enterprises and that as representation on the committee was limited to three for large nations and two and one for smaller nations, the obtaining of facilities could not do more than secure a full attendance. It was also pointed out that at medical congresses all sorts of invitations were accepted. Finally the following motion was adopted:—

> In view of increasing the importance and authority of the annual meetings of the committee by augmenting the number of delegates present, the meeting held at Berne in 1905 decides to appeal to the activity of the National Associations of the Medical Press so that they may endeavour to defray out of their own budgets the travelling expenses of th[illegible] meetings. Pending the completion of such [illegible] secretary of the International Association is at liberty to negotiate [illegible]h the country where the annual meeting w[illegible] facilities for travelling and for the sojourn [illegible] other countries.

The question of finance was then discussed. The general secretary, Dr. BLONDEL, stated that if everyone had paid their subscriptions there should be 2080 francs in hand. All the expenses so far had been limited to a slight amount of printing and a considerable amount of postage, for which he had not claimed reimbursement. It now appeared that through a misunderstanding the treasurer had not asked for any payments. It was resolved that though it was decided at Monaco in 1902 that the different nationalities should pay annually 20 francs for each member whom they had the right to appoint on the committee, yet as this was not confirmed till the Madrid Congress of 1903, the first financial year of the definitely constituted International Association of the Medical Press commenced on Jan. 1st, 1903. The committee, it will be remembered, consists of four members for the Association of the Medical Press in the German language, of three delegates each for the Medical Press Associations of Great Britain, France, Italy, Russia, and the United States of America, of two for Belgium, and of one each for other nations. All these delegates will now be called upon to pay the arrears due.

The fact that no Russian representative was present was discussed and the following memorandum was drawn up, signed by all present, and will be forwarded to the Russian medical press representatives:—

> The delegates of the medical press of Germany, Great Britain, Belgium, Spain, Italy, France, Portugal, and Switzerland, meeting in accordance with their statutes at Berne on April 27th, 1905, regret that anterior misunderstandings may have retarded the affiliation of the Russian press to the International Association of the Medical Press and cordially invite their colleagues of Russia to manifest their desire to join and to nominate forthwith the three delegates whose mission it will be to represent them on the committee.

The morning sitting then concluded.

(To be continued.)

THE NORDRACH COLONIE SANATORIUM.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 1166.)

Nordrach, April 22nd, 1905.

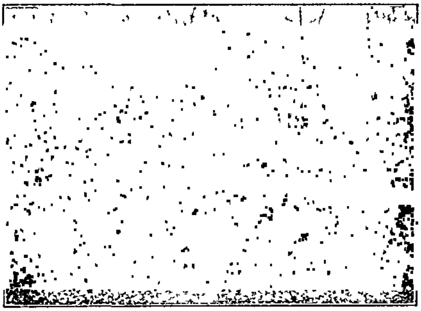
AT Nordrach Colonie exercise plays as important a part in the treatment as the mere fact of being out of doors or of keeping the windows open. It is the morning walk especially, the walk that will create the appetite for the principal meal of the day, that is considered the most important. At 8 o'clock breakfast is served, consisting of pure milk or "coffee" containing more milk than coffee, various sorts of bread, delicious butter, honey, jams, and as much tender cold meat as the patients can eat. But at half past eight everything is swept away and the patients are hurried off each to his allotted task of walking. What is, however, still more surprising is the fact that after dinner, without rest or respite, the walks have to be resumed again. Whatever the weather, rain or snow, the patients must set off for the mountains and the forest. On one occasion an English patient caused much amusement by pathetically pleading for release from this task on the ground that it was Bank Holiday. The plea, however, was not admitted as there was no evidence to show that the habits and customs of the Koch bacillus had in any way been affected by the enactment of the British Bank Holiday Act. In any case it is generally thought that rest should be accorded after meals and that it is essential to eat slowly. There is also an opinion prevalent that it is best to eat little but often. Of course, there are exceptions at Nordrach Colonie as elsewhere, but as a rule these principles are not accepted here. There are only three meals per day. These are devoured at express speed and, with the exception of the evening meal or supper, the patient begins immediately after eating the hardest exercise of which he is capable. Not only are the meals eaten quickly but the food given is that which contains the maximum nutriment in the minimum quantity. There are roast meats, lentils, potatoes, and some, but not much, of the lighter vegetables such as greens and salads. It certainly is a northern diet, there are no "playing with food," no fancy dishes to stimulate flagging appetites, and no loitering over numerous courses. The meals are suited to people of robust health rendered hungry by a bracing climate and unceasing outdoor muscular exertion.

For the ideal sanatorium it is necessary to be surrounded with ideal scenery and a great variety of walks. This and the climate are the chief attractions of Nordrach Colonie. Wood, dale, valley, mountain torrent, babbling brook, majestic mountains, panoramic scenery,—all this abounds and must invigorate and divert especially those who have experienced for long the depressing influence of town life. But the good effects that are thus derived from nature must not be marred by bad sanitation, bad ventilation, or bad food. The sanitation has already been partially described. The drainage is by water carriage into watertight cesspools situated at a considerable distance from the dwelling. These are emptied by an odourless pneumatic system and their contents are carried on to the land. The ventilation, as previously stated, is very thorough and might be described as of hurricane force; but the best measure of all is the complete separation of the various dwellings, each containing but a small number of patients. The Anstalt or largest building, with 20 patients, is about 250 feet from the road and much above it. It is some 400 feet from the Herrn House, with its 16 patients and 150 feet of mountainous ascent from the Swiss cottage, which, however, only holds two patients. In the opposite direction, some 600 to 700 feet away, there is the Roskulla House with nine rooms and no buildings stand between these, the homes of the patients. The Ebler House with five patients and the Finkenzeller with ten convalescents are very much further away. It is this inexhaustible supply of open space and of fresh air that is the most effective measure of hygiene.

Having by all these advantages created an appetite and stimulated the powers of digestion it is all important that the food given should be of the best quality, that is to say, as nutritive as possible. The meat must therefore be tender and succulent. For this it does not suffice to procure the best meat, it is also necessary that it should be hung long enough to become tender. There is an engine-house worked by water power and here ice is made and the meat is kept in a cold storage room. The temperature is just a little above freezing and the meat is hung for about ten days, so that it has not time to lose its flavour and become insipid, like most cold-storage meat, but it does become thoroughly tender. The final point is that the meat should be sufficiently cooked without being overdone. Quality, time of hanging, skill in cooking—these are the three necessary conditions and it must be said that their importance is fully appreciated at Nordrach Colonie. Of as much, if not of greater, importance is the question of milk. Undoubtedly a sanatorium should keep its own cows. It would not be safe to depend on a milk dealer who supplies milk only under such conditions as will yield as large a profit as possible. Milk in the Black Forest is sold at 18 pfennigs the litre. At Nordrach Colonie 10 cows are kept and it would hardly pay to sell their milk at 24 or 25 pfennigs the litre. The barley on which they are fed costs a large sum per annum. If cream is required for cooking purposes, for tea, for cakes, it is purchased in the neighbourhood and not taken from the milk of the cows that are specially fed. Besides barley they are given the best hay and are not often allowed to graze on fresh grass. If the milk-supply should fall short the attendants are given ordinary milk which is bought outside; but the patients always get the milk from the cows especially kept on the estate for them. The difference between this and ordinary milk is very noticeable; and it is the care and the money spent on all these details that constitute the real secret of the Nordrach treatment. It must also be borne in mind that this treatment is subject to modification from hour to hour. The patient's temperature is taken at least three times a day. Three times a day his medical attendant sees him and notes the effects produced by the treatment, the food, and the exercise. Further, the patient sits three times a day at table with his medical attendant who helps him to his food, watches him eat, and hears at the moment itself any complaint that the patient may make in regard to his meals. This process I watched carefully and with interest. Each of the medical attendants sits near to his own patients. The meat is cut in moderately small slices and brought ready cut on a large plate. The medical attendant places on each dish one, two, or three slices and in giving this to the servant indicates for whom it is intended. Thus every detail of the patient's life is carefully watched and controlled from hour to hour. As previously stated, there are no shops, cafés, restaurants, or public-houses accessible where he can get what has not been prescribed. There is but a small kiosk, useful mainly to amateur photographers, a picture of which I, as an amateur photographer, now send to you (see Fig. 3).

Of course, it sometimes happens that a patient is too ill to leave his room, for it must be borne in mind that patients in all stages of pulmonary tuberculosis are accepted. In that case there is a special pan warmed by electricity in each bedroom on which food may be placed and kept warm. Throughout electricity, generated on the estate by the use of water power, is employed. Everything is done to avoid fires that produce smoke, for this does not improve the atmosphere. One or two furnaces for the machinery, the steam laundry, &c., exist and these furnaces are also of use as destructors. The method of dealing with the sputum is simple and effective. An ordinary metallic pail is employed. A newspaper is opened out and placed so as to line the sides of the pail. A certain quantity of sawdust is put into the paper and on this sawdust the spittoons are emptied. The newspaper is closed over the sawdust, lifted and dropped bodily into the furnace, where it is instantly consumed.

FIG. 3.



Kiosk at Nordrach containing the only shop.

Such are some of the main and characteristic features of this sanatorium. From this description it will be easy to see that there is no sort of resemblance between the treatment received by the unfortunate patients at Sandgate and that which is given at Nordrach Colonie.[1]

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Proposed Labour Colony.

A PUBLIC meeting was held a few days ago under the auspices of the Citizens Committee to consider the question of a labour colony for Birmingham and district. The subject has been prominently before the public ever since Mr. Fels offered the guardians land for the purpose. The establishment of such a centre is recommended on the ground that it will enable the Poor-law authorities to provide that employment for the men which, by leading to their physical and moral improvement, will most probably result in their eventually becoming self-supporting. Other advantages claimed for the scheme are that derelict land might be reclaimed by derelict labour and that it would render easy the distinction between those who are and those who are not willing to work. It is admitted that in all probability the colony will be run at a loss [illegible] passed at the meeting urging [illegible] soon as possible a labour col[illegible] similar to those at the Popla[illegible] of the Birmingham, Aston, and King's Norton boards of guardians who were deputed to pay a visit of inspection to the latter colony have issued their report. Without committing themselves to the adoption or the rejection of the scheme they have agreed to gather information as to the number and the class of men suitable for such a colony that the three boards have to deal with and to hold a conference to consider such information.

---

[1] A correspondent points out in another column that possibly the [illegible] benefit of the [illegible] not villages but constitute a popular and populous seaside resort.—ED. L.

Medical Men and School Certificates.

At the last meeting of the Dudley education committee Mr. M. A. Messiter attended as a deputation from the Dudley division of the Birmingham branch of the British Medical Association in reference to the payment by the committee for medical certificates. He remarked that as the law now stood parents were compelled to produce medical certificates in cases of non-attendance of children through illness. Medical men were constantly asked by poor parents to supply these certificates and received no remuneration for the work. Most boroughs in the county were paying for these certificates and he asked that the Dudley authorities should follow their example. The matter was referred to a committee.

The New Dietary Tables at the Solihull Workhouse.

An interesting statement made by the workhouse master at the last meeting of the Solihull board of guardians was that under the new dietary tables, by which each inmate was allowed as much bread as he required instead of a certain fixed weight, there had been a saving of 2033 pounds of bread during the last six months. At the same meeting it was decided to call the children's cottage home which has lately been built "The Woodlands," in order that no pauper taint should be borne by the children living there. The annual return for the board showed that there had been a decrease in the number of paupers from one for every 58 of the population in 1895 to one for every 61 in 1904. The number of pauper lunatics had, however, doubled in the ten years.

The Teaching of Sanitation.

At the last meeting of the Birmingham education committee the report of the technical education and evening schools subcommittee was presented, which recommended the establishment at the municipal technical school of a course of instruction in practical sanitation, together with the formation of a sanitary body to supervise such teaching. Dr. A. D. Heath, in presenting the report, remarked that in Birmingham and the district there were 120 sanitary authorities. There was a great demand for instruction in sanitary science and no machinery at all in the Midlands for meeting the demand.

The Feeding of School Children.

The Order issued by the Local Government Board to the boards of guardians concerning underfed children has been received in Birmingham. It is estimated that there are no less than 6000 such children in the city. The only views I have so far heard expressed are that police-court summonses would be more expeditious than county-court summonses and that the carrying out of the Order will prove an expensive matter unless the teachers are utilised for obtaining the necessary information.

May 2nd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Death of Dr. J. E. Dutton.

THE sad intelligence of the death of Dr. J. E. Dutton at Kosongo in the Congo reached Liverpool on April 27th. The deceased gentleman was actively engaged in the investigation of trypanosomiasis and tick fever at the time of his death.

Liverpool Port Sanitary Authority: Last Year's Work.

The report for 1904 of Dr. E. W. Hope, medical officer of health to the port sanitary authority of Liverpool, speaks of the careful inspection made of ships which arrived during the 12 months from ports in the East infected with plague, cholera, and small-pox, and of the directions given for cleansing and disinfecting the vessels. Rats play an important part in the dissemination of plague, and during the year 4632 were caught on board 139 ships and examined bacteriologically. Experience in recent years shows that if ordinary precautions are taken the risk of the spread of plague in European ports is very small, probably no greater than in the case of small-pox. Plague is still prevalent in many parts of the world. In Europe no extensive outbreak had occurred during the year. Comparatively few cases of small-pox arrived in the port during the year. The infectious cases landed during the year numbered 99, being exactly the same number as in the previous year. 3522 vessels were inspected, an increase of 520 over the previous year. On board these vessels 4821 nuisances were discovered, 64 per cent. of which were due to inattention to cleanliness. The number of emigrants who sailed from the port was 274,584, of various nationalities. Only 36 out of that large number were found to be suffering from infectious disease, such as children affected with measles, scarlet fever, and chicken-pox. The number rejected on account of non-infectious sickness was also small and the temporary ailments from which emigrants suffered and which resulted in postponement of their journey do not call for special comment. 15 cases of beri-beri which were discovered were treated in the tropical ward of the Royal Southern Hospital.

Death from Cerebro-spinal Meningitis.

An inquest was held on April 22nd on the body of a tailor's cutter who died at the Royal Infirmary on April 18th. According to the evidence of the widow of the deceased it appeared that on March 16th he had had a dispute with his employer's son who dragged him round the shop and shook him. On the way home he had felt too weak to walk and had to be assisted by a friend. The following morning he complained of weakness and pains in the head. Corroborative evidence was given by the tailor's manager as to the struggle. Mr. J. D. McFeely gave a brief history of the symptoms of the case up to the date of the deceased's removal to the Royal Infirmary. He had complained frequently of pains in the left ear and there was a slight tendency to inflammation of the brain. When he recommended his removal to hospital he considered that an abscess was at the root of the trouble. Dr. Hick, house surgeon at the Royal Infirmary, said that when the deceased was admitted to hospital it was agreed by his senior colleagues that he was suffering from meningitis of the brain and spinal cord. A post-mortem examination revealed the fact that death was due to cerebro-spinal meningitis. There were no signs of injury. Cases of this sort had usually no relation to injury and arose from infection admitted through the nose. In reply to the coroner, Dr. Hick said that it was similar to the disease imported from America and that the post-mortem examination did not reveal an abscess at the left side of the brain. A verdict in accordance with the evidence of Dr. Hick, ascribing death to cerebro-spinal meningitis, was agreed upon, the jury adding that there was no evidence to show whether it was due to an injury or to an abscess set up by an injury. At the meeting of the health committee on April 27th Alderman Grant asked Dr. Hope, the medical officer of health, whether he had any information regarding the case of supposed "spotted fever" which occurred at the Royal Infirmary. Dr. Hope pointed out to the committee that the name "spotted fever" was rather a loose term and was applied to a variety of diseases, including typhus fever, which, of course, was highly infectious and one from which Liverpool was, unfortunately, seldom, if ever, entirely free. With regard to the disease which had been prevalent in New York they had no experience of it at all. The term cerebro-spinal meningitis was applied to the disease which the name implied—inflammation of the membranes of the brain and spinal cord. Cases occurred year by year; he had no recollection of a year passing without a death from it. It had no connexion, so far as he knew, with the disease which had been prevalent in New York.

Leigh Infirmary: Laying the Foundation Stone.

The foundation stone of the Leigh Infirmary was laid on April 29th by Alderman Greenough in the presence of a large gathering. The site of the hospital is situated on the Atherton and Tyldesley side of Leigh within a few minutes' walk of the centre of the town. The site is three and a quarter acres in extent, about two and a quarter acres having been generously given by Lord Lilford and the remainder was leased from his lordship. There would thus be space for 40 beds in wards of one storey or 120 beds in wards of two storeys. The present scheme provided for a two-storeyed ward to contain 15 beds for men and 15 beds for women and children. In the administrative block the out-patient department would be temporarily housed. Alderman Greenough announced that he had that day received promises of about £250 in subscriptions, &c., and as an earnest of his sympathy with the movement he would give a further £500 to the endowment fund. The donations to the infirmary at present reach the sum of £11,000. In the evening 35 guests were entertained at dinner by Alderman Greenough. It was stated that in order to provide for the maintenance of the infirmary an effort would be made to get the 14,000 Leigh workpeople to subscribe 1*d.* a week each, as was done at Wigan, where £800 were received annually in this way. The £750 now subscribed from the Leigh collieries to the Wigan Infirmary will probably be diverted to the Leigh Infirmary..

May 2nd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

West Wales Sanatorium.

AT the meeting which was held at Cardiff in 1901 for the purpose of establishing a branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis for South Wales one of the most enthusiastic supporters of the scheme was Dr. Douglas A. Reid, the medical officer of health of Tenby, and he was so successful in inspiring his neighbours with a similar enthusiasm that very shortly afterwards a branch of the association was formed for the three western counties of Carmarthen, Pembroke, and Cardigan, where at the census of 1901 there was a population of 284,311 persons. The necessity for taking steps to combat the disease in these counties is forcibly demonstrated in the last annual report of the Registrar-General. In this report Dr. J. F. W. Tatham, in his letter to the Registrar-General on the causes of death, says: "In the report for 1902 allusion was made to the high phthisis mortality prevailing in parts of Wales...... The present report shows that in the succeeding year phthisis was much more fatal among both sexes in Carmarthenshire, Pembrokeshire, and Cardiganshire than it was in the remaining counties of the South Wales group. After correction for age and sex the death-rate in these three counties together was equal to 1855 per million among [illegible] both of these rates be[illegible] corresponding rates for [illegible] and still more in excess [illegible] counties of this group." [illegible] more striking when the records of each county are dealt with separately. Taking both sexes together the rate in Carmarthenshire was equal to 1487 per 1,000,000, in Pembrokeshire to 1536 per 1,000,000, and in Cardiganshire to 2121 per 1,000,000, this last being a higher rate than that which prevailed in any of the other English or Welsh counties. Very soon after the formation of the West Wales branch of the National Association it was decided to erect a sanatorium and a scheme was drawn up to provide accommodation for 28 patients, of whom 20 should pay 10*s.* weekly and the remainder a larger sum. The lords lieutenant of the three counties and of Haverfordwest, which is a separate lieutenancy, took an active part in securing funds and have been appointed trustees of any moneys collected. Several sites more or less suitable were offered by various landowners, some of whom placed any portion of their estates at the disposal of the selecting committee, and eventually one of 14 acres was chosen and has been leased for 999 years from Colonel Davies-Evans, the lord lieutenant of Cardiganshire, at a yearly rental of £11. It is situated in Carmarthenshire overlooking the vale of the Teivy and is about three miles from Llanybyther railway station. It has a sandy soil on shale and rock and is at a height of 848 feet above sea level. There are an abundant supply of water and a large number of trees. On April 26th H.R.H. Princess [illegible]sed buildings [illegible] be expended. [illegible]vards this sum [illegible] to make contributions from the county funds. On April 25th the Cardigan council decided to contribute £500 and to make an annual grant of £150 on condition that the council should have two members on the board of management and the right to nominate two patients to free beds. The other councils have not yet come to any decision in the matter.

Carmarthen Asylum.

The rate to be charged during the current six months for the maintenance of pauper lunatics in the three counties asylum at Carmarthen has been fixed at 9*s.* 0½*d.* per head weekly.

The Medical Officer of Health of Gloucester.

When Dr. John Campbell a few months ago resigned his position as medical officer of health of the city of Gloucester the corporation decided that his successor should devote his whole time to his official duties and proposed to pay a salary of £400 per annum for the combined posts of city medical officer of health, superintendent of the infectious diseases hospital, and medical officer of health to the port sanitary authority. The Local Government Board, however, refused to sanction a less salary than £500, with the result that the council resolved to permit private practice and to give a salary of £250. There were 26 applicants for the appointments and two appeared before the council on April 26th, when Mr. William M. Hope, who has practised in the city for 15 years, was elected by 26 votes to 9.

Health Report for Bath.

The medical officer of health of the city of Bath (Dr. W. H. Symons) states in his annual report that the corrected death-rate during 1904 was 13·3 per 1000 and the infantile mortality rate 111 per 1000 births. Although the deaths among young children are fewer than in many parts of England Dr. Symons thinks that a still greater reduction might be made and refers to the good work which is being done elsewhere by female inspectors one of whom might be usefully employed in Bath. There were 45 deaths from pulmonary tuberculosis, a disease which is voluntarily notifiable in Bath, 76 cases thus coming to the notice of the medical officer of health during the year,

Plymouth Lunatic Asylum.

At a special meeting of the visiting committee of the Plymouth Lunatic Asylum, held on April 28th, it was reported that the two new wings, which will provide accommodation for 140 patients, are now practically complete. The cost of the building has been about £26,000. The committee decided to proceed at once with the erection of a new storey (to contain 60 beds) over the existing building. The cost of this is estimated at £6000. When the entire scheme is completed the asylum will have accommodation for 400 patients.

May 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Graduation Ceremony at Glasgow.

THE graduation ceremony at the University of Glasgow took place on April 18th in the Bute Hall before a crowded audience. As is usual at this time there were no candidates for the degrees of M.B., Ch.B., as the great bulk of the medical students come up for degrees at the summer graduation ceremony, but the degree of M.D. was conferred upon four graduates. The honorary degree of LL.D. was conferred, among others, upon Professor A. Crum Brown of Edinburgh and Sir William Whitla of Belfast.

Kilmun Seaside Homes.

These homes, conducted by the Glasgow Abstainers' Union, after renovation and extension at a cost of £2500, have recently been reopened by Sir John Ure Primrose, Lord Provost of Glasgow.

The Glasgow Hospital Sunday Fund.

This fund has recently been divided amongst the hospitals. The total amount collected during the past year was £4801 8*s.* 9*d.* and the average amount per church was £10 19*s.* 4*d* The sum was allocated as follows: Royal Infirmary, £2174 9*s.* 11*d.*; Western Infirmary, £1713 17*s.* 3*d.*; and Victoria Infirmary, £651 13*s.* 3*d.* The chairman, in moving the adoption of the report, referred to the possibility of infirmaries taking in paying patients at a more moderate scale than could be obtained in private homes and pointed out the difficulties which would arise if this were done. At the same time he acknowledged how largely and munificently the working people contributed to the funds of the infirmaries.

The Glasgow Maternity Hospital.

This charity is making an appeal for subscriptions in order to enable the board to proceed with the scheme for enlarging the hospital. The directors have already got £30,000, but £80,000 are needed to complete the alterations. This appeal will no doubt commend itself to all who have any knowledge of the work done in the Maternity Hospital. Quite apart from its value as a charitable institution its position as a hospital for the teaching of practical obstetrics demands that adequate accommodation should be found for the cases and for teaching purposes. In a city which is unfortunately notorious for the prevalence of rickets one would expect that complicated cases of labour among the lower classes would be very frequent, and the statistics of the hospital bear this out. This fact, together with the number of patients who are admitted each year, renders the hospital of great value in the training of students and nurses. When the requisite money is forthcoming and the new buildings are erected the hospital should take its position as a teaching school second to none of its kind in the United Kingdom.

The Diagnosis of Insanity.

That there is sometimes considerable difficulty in certifying as insane a patient whose morbid characteristics are not present in any very marked degree will be denied by few practitioners of any experience. It is interesting to note that this difficulty is shared, at least in some cases, even by experts in psychological medicine. A petition which recently came before the sheriff court at Glasgow illustrates the divergence of opinion which may arise in such a case. The case in point was that of a young married woman who had been convicted of theft. The procurator-fiscal petitioned the sheriff to declare that she was of unsound mind and a danger to the lieges and that she be handed over to Govan parish council to be detained in an asylum. On behalf of the petition he brought forward three expert witnesses to certify that she was a dangerous lunatic. The parish council, on the other hand, took up the position that the case was an attempt on the part of the Crown to get rid of its liability. The woman was arrested on the charge of theft and if she was merely insane the Crown would require to keep her. The Crown, however, tried to make out that she was a dangerous lunatic and to saddle the monetary responsibility on the parish council. On behalf of the parish council the superintendent of Hawkhead Asylum stated that the woman had been a patient in the asylum but was dismissed cured in November, 1904. While under treatment she had showed no signs of violence and, in his opinion, although weak-minded, she was not at present insane. After a lengthy debate the sheriff dismissed the petition reserving the question of expenses.

Nairn Hospital.

A meeting of the directors of the Nairn Town and County Hospital was held on April 27th, Mr. J. S. Robertson, the chairman, presiding. A discussion took place on the question of a sewage connexion to the town sewer from the new hospital buildings. Some time ago the directors applied to the town council for a connexion, an application which was granted on condition that the directors would pay for the laying of a storm overflow pipe at Church-street and that the town council would have the right to make connexions on the pipe proposed to be laid between the hospital and the town sewer. The directors afterwards withdrew this application and submitted another, asking for a private connexion and also asking the council to withdraw its condition as to a storm overflow pipe. The council agreed to withdraw the condition as to the overflow pipe but adhered to the previous condition that it should have the right of connexion with the hospital sewer. The chairman moved that they should again approach the town council asking it to withdraw this condition also. He thought it was rather hard on a charitable institution such as the hospital that the town council should impose such a condition when the hospital committee would have to spend about £400 in laying this sewer. Mr. Donaldson, solicitor, seconded the proposal. Provost Dallas moved that the offer be accepted. He thought it would be absurd to expect the town council to grant such a connexion to its main without attaching any conditions to it. What interest, he asked, could the directors possibly have in a pipe which was laid seven or eight feet below the ground? On the other hand, if the town council took it over the directors would be relieved of all responsibility. The provost's proposal did not find a seconder and the chairman's motion consequently became the finding of the meeting.

May 2nd.

IRELAND.

(From our own Correspondents.)

The General Medical Council.

Although the election of the Direct Representative for Ireland on the General Medical Council will not take place until next year, the question is exciting the greatest interest in medical circles and is being discussed all over the country at the various medical gatherings. Sir William Thomson, the present Direct Representative, will seek re-election and the only other candidate, up to the present, is Dr. L. Kidd of Enniskillen. The question mainly at issue is whether or not Dublin is to continue, as in the past, to supply the whole seven Irish representatives or are the provinces to be enfranchised (that is, to have a member to represent their interests). Already it is evident that Dr. Kidd will have an immense amount of provincial support and it is believed that a very large body of the profession in Dublin (both teachers in the schools and those unconnected with any of the colleges or licensing bodies), recognising the fairness of the claims of the provincial general practitioners, will support Dr. Kidd's candidature. There is also an important body in the electorate who, while not at this early period in the canvass committing themselves to any candidate, are agreed that they will support only a provincial member of the medical profession.

The Infectious Diseases Hospital, Belfast.

Several inhabitants of Windsor district, in Belfast, have presented a memorial to the Local Government Board asking it to direct the Belfast corporation to stop the construction of the sewage works for conveying the sewage of the infectious diseases hospital into the main drains of Belfast and to comply with the provisions of the Public Health Act by giving the statutory three months' notice in the public papers to allow objections to be lodged. It is also desired that the Board will direct the corporation before proceeding any further with the work to have the condemned ventilating traps in Balmoral-avenue (into which the sewage is proposed to be emptied) closed and ventilating shafts connected with the sewer erected at convenient places and at proper heights, or some other approved method of sewer ventilation, such as the Reeves system, which, it is said, works satisfactorily in Edinburgh and other large cities.

Queen's College, Belfast.

Professor J. W. Byers has been appointed to represent Queen's College, Belfast, at the International Congress of Obstetrics and Gynæcology to be held in St. Petersburg next September.

The Irish Medical Association.

At the coming general meeting of the Irish Medical Association, to be held in Killarney on June 7th, it has been decided that a scientific paper on a selected subject of interest to the great body of the profession be read, followed by a discussion. This is a great step in advance on the business of former meetings.

May 2nd.

PARIS.

(From our own Correspondent.)

Nitrite of Amyl in Tuberculous Hæmoptysis.

At the meeting of the Hospitals Medical Society which was held on April 14th M. Rouget read a paper dealing with the good effects to be obtained from the inhalation of nitrite of amyl in the hæmoptysis which occurs in the course of pulmonary tuberculosis, whether in the stage of consolidation or in that of softening. M. Rouget gave an account of the results obtained by this method in ten patients and they were remarkable. In one case the hæmorrhage could not be checked by any other remedy. The nitrite acts indirectly on the pulmonary circulation by lowering the blood pressure owing to its causing peripheral arterial dilatation. M. Rouget has employed this physiological action not merely to stop hæmorrhage but as a preventive, by administering it as soon as the warnings of an approaching hæmorrhage—namely, a disagreeable taste in the mouth and a feeling of oppression in the chest—are noticed.

Treatment of Gonorrhœal Arthritis of the Knee.

At the same meeting of the above society M. Queyrat discussed the treatment of gonorrhœal arthritis of the knee. In his opinion it is to aspiration and to the application of the actual cautery that we must look for the best method of obviating future ankylosis of the joint. He cited as an example the case of a man, aged 31 years, whom he had treated by aspiration followed immediately by the actual cautery. The joint was then enveloped in cotton-wool and the limb immobilised on a back-splint. Ten days later the cautery was again applied and within a very short time afterward the joint was passively moved Within 33 days from the commencement of the treatment the patient was well and could mount a bicycle

Public Gardens

The administrative committee of the Alliance d Hygiène Sociale has just devoted a sitting, M Casimir Perrier being in the chair, to the consideration of a report by Dr Letulle relative to public gardens and in particular to the use for this purpose of the dismantled fortifications of Paris and of other towns in the department of the Nord The committee passed resolutions to the effect that every town should reserve within its boundary, or immediately outside it large open spaces which should be used as playgrounds for both children and adults, that Parliament should not authorise the dismantling of the fortifications of a town unless a guarantee were given that the town would undertake to preserve the land thus set free as an open space which would benefit the hygiene of the town, and that at Paris in particular the city and the riverside parishes (*communes*) should profit by the dismantling of the fortifications and by the suppression of the *one militaire,* to reserve large open spaces for laying out as public gardens These resolutions also have been adopted by the Society of Public Medicine and of Sanitary Engineering

Semi resection of the Elbow joint for Ankylosis

At the meeting of the Society of Surgery which was held on April 12th M Kirmisson gave an account of the case of a young girl on whom he had performed the above operation She had complete ankylosis of the elbow joint at a right angle As she was a musician and was anxious to continue her piano and violin exercises M Kirmisson proposed to resect the joint Eventually however, he only removed the olecranon and a portion of the articular surface of the lower end of the humerus (*apophyse humerale*) The result was excellent, the movements of the joint being almost as free as if it were normal

Grafts from the Lining Membrane of Egg shell

At a recent meeting of the Therapeutical Society M Amat read a paper upon the Use of the Lining Membrane of Egg shell as a Skin Graft M Amat has for a long time past advocated the employment of this membrane and he brought two new cases to the notice of the meeting The one was that of a young girl suffering from a wound of the foot consecutive to a burn and the other that of a man aged aricose ulcer of the leg There e wounds were covered with eight different grafts of egg to the two ulcers respectively, the grafts being about one square centimetre in size These were covered with tinfoil both to fix them and to act as guide to their position The whole was kept in position by a dry aseptic dressing Four days later when the dressing and the tinfoil were removed there were seen two small opalescent points on the foot of the girl and three on the leg of the man On the following day these points had sent out processes which reached to the epithelial borders of the ulcer Five more grafts were placed on the foot of the girl but only one "took M Amat considered that the cicatricial process was much stimulated by the grafts As egg shell membrane is so easy to obtain it is a pity that its use is not more widely spread more especially as the cicatrix obtained by its use is supple

The Students and the Faculty of Medicine

In consequence of the closing of the Paris Faculty of Medicine and of the events leading up to it which I have already described the committee of the general association of students has held a meeting M Liard, the vice rector has been approached by the president of this committee as well as by a deputation from the Association Corporative des Étudiants en Médecine the object being to obtain the vice rector s support to a petition which they were about to present to the Minister of Public Instruction praying that the reception of theses and the final examinations for graduation might be proceeded with On the advice of M Liard the petition was submitted to the Minister of Public Instruction who immediately authorised the holding of two examinations for students whose cases were exceptional The deputation having then presented to the dean of the faculty a list of ten candidates for whom it was of material consequence that their theses should receive consideration as soon as possible, M Debove, the dean, immediately forwarded these requests, with his approval of them, to the vice rector The students moreover, ask for certain modifications in the curriculum *(programme d études)* and in the examinations—namely, that more importance should be given to medicine and less to accessory subjects, that the two chairs of physics and chemistry should be converted into two chairs of clinical medicine, that the system of paying fees for instruction in therapeutics should be abolished, and that the professors should be required to conduct their practical courses The classes, which are arranged specially for students and for which fees are paid (*cours de perfectionnement*) have been resumed

Reduction of Oxyhæmoglobin

At a meeting of the Academy of Sciences held on April 10th M Lépine and M Boulud said that in consequence of the statements which had been made as to the length of time required for the reduction of oxyhæmoglobin in a fatal case of surgical shock after prolonged anæsthesia they had undertaken a systematic research on the subject They endeavoured to ascertain if the oxyhæmoglobin in different samples of abnormal blood was reduced in the same time by the same reducing agent (ferrous sulphate being used in each case) employed in an amount exactly proportional to that of the hæmoglobin After numerous trials made with a view to the selection of a method they were able to establish the following facts The time required for the reduction of the oxyhæmoglobin under the conditions of their experiments was about 20 minutes In anæmia the time required for reduction (with a quantity of the reagent strictly proportional to the small amount of hæmoglobin in the blood) was greatly increased M Lépine and M Boulud have known it to exceed an hour Prolonged inhalation of chloroform or ether also increased the time required for reduction Infection of the blood with various microbes including a very virulent staphylococcus, appeared to be without sensible influence

May 1st

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Medical Progress in the Philippines

AT the recent meeting of the Philippine Islands Medical Association many interesting facts appeared in regard to the progress of medical education and practice in that country The first event of the meeting was the inspection of the new Government laboratory which was just completed The building cost the insular Government $108 000 and is the most completely equipped building of the kind in any oriental country The Secretary of the Interior, the Hon Dean C Worcester under whose direction the building was erected, stated that from a practical standpoint it was of the greatest economical value, because experience proved that until science had come to the rescue the white race had never been able to inhabit the tropics successfully and that much more work was required in this direction so that the danger might be still further reduced He added that a great deal had been accomplished especially with regard to health conditions which made it possible for the white man to live in the tropics with almost the same security as he inhabited the temperate zone particularly was this true if excesses were avoided and a clean moral life was followed The statistics of Manila showed that the death rate among the white race was 9 75 per 1000 while that of the natives was 53 per 1000 The Secretary was often distressed to see persons dying from diseases which would have yielded readily to medical or surgical aid had it been at hand, and even in Manila 50 per cent of the deaths recorded occurred without medical attendance Dr John R McDill delivered the president's address in which he said that, with the exception of some intestinal disorders which were being prevented, the treatment of the diseases met with was as successful as elsewhere when hospital care was available Pride in the achievements of the insular board of health was shared in by the public and the profession alike He regretted that while every effort had been made to get the cooperation and the participation of the native physicians in the meetings of the Medical Society thus far the effort had met with very limited success The Filipino medical students had two striking characteristics, viz (1) the astonishing capacity to absorb and to expound theory, and (2) the fact that the ablest members of the profession have always been among the foremost political leaders of their country. The time when they could expect their coöperation would, perhaps, come only when the generation which is now being educated came to the front. There are only about 360 duly licensed physicians in the islands and 217 of these are in Manila. These figures mean that while Manila has one physician for every 1013 inhabitants, in the provinces there is only one physician for every 51,786 persons, or, in other words, one medical man for each 430 square miles. The hope of the profession lies, in his opinion, in the establishment of a first-class medical school where the Filipinos may be properly educated.

Castration as a Preventive of the Propagation of Idiocy.

The legislature of the State of Pennsylvania has passed a Bill directed towards the prevention, by castration, of procreation on the part of idiots and imbeciles in public institutions. The governor of that State, however, has vetoed the measure, thus preventing the legalisation of this much-debated method of limiting the number of idiots. The Governor contends that the nature of the intended operation is not sufficiently described in the Bill, its only qualification being that it shall be the "safest and most effective" in the judgment of a neurologist, a surgeon and a physician. While he thinks the most effective method would be decapitation he doubts the popularity of that preventive measure. His real objection to the Bill appears when he states that men of science, like all other men whose experiences have been limited to one pursuit and whose minds have been developed in a particular direction, sometimes need to be restrained. The defect of such a law would, in his opinion, lie in the fact that a surgeon might possibly be so eager to advance in skill as to be forgetful of the danger to his patient.

Conference of American Anatomists.

The Wistar Institute of Anatomy of Philadelphia recently invited the leading anatomists of the United States to meet in conference with the managers of that institution. The *objects of the conference were to discuss the advisability* and means of organising central institutes for the promotion of research in the different subdivisions of anatomy, such as physical anthropology, comparative anatomy, topographical anatomy, embryology, histology, and neurology, and also to establish relations with similar institutes abroad. The Wistar Institute is splendidly equipped, has a broad plan of foundation, and is devoted to advanced work only, with no undergraduate teaching; hence it is proposed by anatomists to utilise this institution as an anatomical centre where committees may meet from time to time, the work be collated, and research material collected and prepared for investigation and sent about the country to qualified investigators. If the plan is carried out the institute will do for all the great universities of this country certain important lines of work which no other institution can attempt and carry to a successful conclusion.

Changes in the Teaching Staff of Johns Hopkins University.

The withdrawal of Professor Osler from the Johns Hopkins University has necessitated the reorganisation of its teaching staff. The Professorship of Clinical Medicine has been one of the most important chairs in the medical department and has been rendered famous by the teachings of Professor Osler. This position has been filled by the elevation of Dr. Thayer, a graduate of the university and an assistant of Professor Osler. Professor Thayer has been a successful worker in the field of clinical medicine and gives promise of maintaining the reputation of his department. The selection of Professor Lewellys Barker, the head of the department of anatomy in the University of Chicago, for the chair of General Medicine, is a surprise. Professor Barker has long had an enviable reputation as a worker in the field of anatomy and allied branches of science but is quite unknown in the department of general medicine. He has, however, all of the elements necessary to success in this new field of work and there is no doubt in the minds of his friends that he will not disappoint those who were instrumental in his selection. Previously to his appointment to the professorship of anatomy in the University of Chicago he was associate professor of anatomy in the Johns Hopkins University and assistant resident pathologist to the Johns Hopkins Hospital.

Eddyite Treatment is Adjudged to be the Practice of Medicine.

The Supreme Court of Ohio holds that the giving of "Christian Science" treatment for a fee for the cure of disease is practising medicine within the meaning of the statute regulating such practice in that State. The court says that the right to practise medicine has been so long and so universally subject to State regulation that it might almost be said to be not an absolute right but a privilege or franchise. Assuming that it is an absolute right it must be conceded to be subject to such reasonable regulations and conditions as the State in the exercise of the police power may prescribe. The court fails to find anything in the present Act that discriminates against Eddyism. It does not provide for a special examination and limited certificate for the Eddyite practitioner but he may obtain a certificate to practise medicine upon the same conditions as any other person and there is nothing in the Act requiring him to use the knowledge after he has acquired it. The statute provides that—

> Any person shall be regarded as practising medicine or surgery or midwifery within the meaning of this Act who shall ...... prescribe or who shall recommend for a fee for like use any drug or medicine, appliance, application, operation, or treatment, of whatever nature, for the cure or relief of any wound, fracture, or bodily injury, infirmity, or disease.

The court quotes from Dr. O. W. Holmes, the poet-physician, "Disease is to be treated by anything that is proved to cure it." The court concludes: "So that the use of the words 'of whatever nature' ...... are quite significant and this court has no doubt the legislative intent was to bring within this definition every person who for a fee prescribed or recommended a cure for disease, even though the cure was to come not from himself but, through his intercedence, from God."

April 24th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A New Scheme for the Supply of Water to Calcutta.

THE city of Calcutta during the last two years has been *suffering from a deficiency of filtered water* partly due to the installation of a constant in place of an intermittent supply, partly to wastage, and partly to increased requirements. It is estimated that about 20 gallons per head per day have been brought into the city. This supply is taken from the river Hooghly about 20 miles above Calcutta, is filtered at the works close by the intake, and is then brought into the city by iron mains. In consequence of the level ground a great deal of pumping has to be done to distribute it throughout the city and the pressure is so low that filtered water will barely reach the first floor of houses. To overcome these inconveniences it is proposed to have a huge raised storage reservoir to which a set of engines will be constantly pumping the water as it arrives from the mains and from this reservoir to distribute the water by the power of gravitation, thus doing away with three district pumping stations, obtaining greater pressure, and avoiding the dangers of the present district underground storage tanks. By the Municipal Act the constant supply must be established so that this change will be completed gradually. Meantime a larger quantity of water is being brought into the city by increasing the pressure in the mains from the waterworks. This increase, however, will not be sufficient for the new scheme, a further modification of which has just been proposed—viz., to do away with the subsidiary supply of unfiltered water and to substitute filtered water throughout the town. The latest scheme proposed by the chief engineer contemplates the erection of a 10,000,000 gallon reservoir and to supply 50 gallons per head per day instead of at present about 20 gallons. The supply of unfiltered water is considered a danger to the town. It probably is; but the danger from this source is infinitesimal compared with that from the thousands of filthy tanks (it is estimated that there are over 5000 tanks in the area of the city) which are used not only for washing clothes but for drainage of the privies from surrounding huts. Moreover, the natives go down in thousands to the river to bathe and to fetch the holy water and comparatively few have access to the unfiltered supply brought into the city for road watering and flushing purposes. The new scheme for more pure water is a grand one, not only from a sanitary point of view but in its engineering features. The expense, however, will be enormous and 50 lakhs of rupees will not cover it.

A Higher Record in Plague Mortality.

A further and still more terrible record in plague mortality throughout India is returned for the week ending

April 1st. There were 57,702 deaths and 65,789 cases were reported. Even this probably does not represent the whole truth. Last week 53,895 deaths were recorded. In the United Provinces 23,387 deaths occurred, in the Bombay districts 3056, in Madras districts 81, in Bengal 9703, in the Punjab 19,015, in Burma 72, in the Central Provinces 338, in the Mysore State 104, in the Hyderabad State 470, in Rajputana 1269, and in Kashmir 101. The latest weekly returns for Calcutta give 712 deaths.

The Instruction of Natives in First Aid to the Injured.

The recent demonstration in first aid to the injured held in Calcutta under the auspices of the local centre has shown that the natives of India can be usefully instructed in this work. There were competitions amongst native students who had been through the regular course of training and other competitions among the native constables who had been instructed in the junior course. All these competitions were keenly contested and were very creditably performed, but the general impression is that where real assistance is required native help would not be forthcoming. Perhaps the knowledge of what to do will give these competitors at any rate the necessary courage.

The Earthquake.

The terrible earthquake in Dhamsala and adjoining places has called for medical aid on a large scale. Some curious injuries are reported and, as usual, some miraculous escapes. The exhumation of buried bodies has been a great undertaking and the military have been called in to assist. The stench of the dead is described as having been very great as some time elapsed before removal could be effected. At Landour a house was moved bodily down the hillside and anchored safely on a ledge a short distance below, the inmates being quite unconscious of the sudden change. *Many of the tea estates have been destroyed.* Most of the injured have been more or less bruised by falling stones. People were in bed at the time and got crushed under falling roofs and walls. A succession of slight shocks followed the disastrous one.

April 14th.

Obituary.

JOSEPH EVERETT DUTTON, M.B., CH.B. VICT.

It is with great regret that we announce the sudden death of Dr. Joseph Everett Dutton, Walter Myers Fellow of the Liverpool School of Tropical Medicine, at Kosongo in the Congo, on Feb. 27th, while actively engaged in the investigation of trypanosomiasis and tick fever. In 1903, Dr. Dutton, accompanied by Dr. J. L. Todd, proceeded to the Congo to investigate trypanosomiasis and other tropical diseases. Towards the end of 1904 they had reached Stanley Falls and independently they were able to demonstrate the cause of tick fever in man, a discovery made a few weeks previously by Ross and Milne in the Uganda Protectorate. Further, they were able to show the transference of the disease from man to monkeys by means of a particular species of tick. During these investigations both observers contracted the disease. A letter received from them in Liverpool was dated Kosongo, Feb. 9th, when they both appeared to be in excellent spirits and were on the return journey but since then the news of the sudden death of Dr. Dutton has reached this country through the Belgian Government, and later Baron Liebricht sent sincere condolences from the Congo Free State Government by telegram.

In the death of Dr. Dutton the Liverpool School of Tropical Medicine and the University of Liverpool have suffered the loss of a most brilliant graduate. Although quite young in years Dr. Dutton had already won a recognised position throughout the scientific world and as recently as last October Professor Koch, in an address before the anniversary meeting of the Berlin Medical Society, exhorted all nations to lend assistance to the work of combating trypanosomiasis in man so successfully conducted by the expeditions under Bruce, Dutton, and others. Educated at the King's School, Chester, he proceeded to the University of Liverpool, w [illegible]
and in 1897 he was appointed [illegible]
in Pathology which gave hi [illegible]
for research. This fellowship, the first of its kind which was established at Liverpool, has proved of the greatest service in encouraging original study, for Dutton succeeded as Fellow Lieutenant S. R. Christophers, I.M.S., now Director of the King Institute of Hygiene, Madras, who held the fellowship in 1896; Dr. H. E. Annett, the present lecturer in comparative pathology in the University and superintendent of the Farm Station of the Liverpool Institute of Comparative Pathology, who held it in 1895; and Dr. E. E. Glynn, the present lecturer in clinical pathology, who held it in 1899.

After qualifying as M.B., Ch.B. Vict., Dr. Dutton acted as house surgeon to Professor Rushton Parker and house physician to Dr. R. Caton at the Liverpool Royal Infirmary and in 1901 he was elected to the Walter Myers Fellowship in the Tropical School. His first expedition to West Africa took place in 1900, when with Dr. Annett and Dr. Elliott of Toronto he visited Nigeria in order to study the bionomic of the anopheles and measures generally for the prevention of malaria. Two reports were issued as the result of this expedition, one dealing with anti-malaria sanitation and the other consisting of one of the most complete monographs upon filariasis hitherto published. In 1901 he proceeded alone to the Gambia and drew up a most comprehensive and useful report with regard to the prevention of
[illegible] the colony he won to a remark-
[illegible] regard of all whom he met and
[illegible] to the success of his expedition.
It was during this expedition that he identified in the blood of a patient of Mr. R. M. Forde, the medical officer of Bathurst, a trypanosome belonging to a group of animal parasites which had hitherto been only found in animals. He accurately described and named it. Subsequently he found the same organism in numerous other cases in the Gambia and elsewhere. It can hardly be doubted that this discovery of the first trypanosome in man by Dr. Dutton was an important factor in leading to the discovery of the cause of sleeping sickness, which was subsequently shown by other observers to be due to the same parasite. In addition to his discovery of trypanosoma Gambiense he also described several other trypanosomes new to science. In 1902 he proceeded with Dr. Todd to the Senegambia and drew up a report on sanitation which was presented to the French Government and further papers on trypanosomiasis were published. The present expedition to the Congo was sent out in 1903. Dr. Dutton was accompanied by Dr. Todd and Dr. C. Christy, the latter returning to England in June, 1904. It was evident by the last letter which they sent to the committee of the Liverpool School of Tropical Medicine that they had made many valuable observations whilst tracing sleeping sickness along the river banks and in their investigations upon the nature of tick fever and filariasis and no doubt the publication of these will soon follow.

It will be seen from this brief account of Dutton's career that although under 30 years of age he had accomplished much good and strenuous work and had advanced in a most striking manner our knowledge of certain departments of medicine. Medical science is deprived of one of its most promising younger men, the city of Liverpool of a most gifted student, and his colleagues in the University and the Royal Infirmary have lost one who combined with a great intellect a charming personality which made him beloved by all.

A special meeting of the Liverpool School of Tropical Medicine was held on [illegible]
being in the chair. [illegible]
pathetic terms, expres [illegible]
the premature death of so distinguished a man of science, and on his motion, which was carried unanimously, the following resolution was recorded :—

"T [illegible] Medicine desire to place on
[illegible] he relatives of the late Dr.
[illegible] of that promising scientist
[illegible] f the school. The school will
[illegible] go with which Dr. Dutton
[illegible] althy regions in West Africa
[illegible] Dr. Dutton served on the
[illegible] sited Southern and Northern
[illegible] n, which visited the Gambia
[illegible] visited Senegambia in 1902;
[illegible] the twelfth expedition, which
[illegible] rypanosomiasis, sleeping sick-
ness, &c., in the course of which his lamentable death has now occurred. The valuable discoveries made by Dr. Dutton, especially that of identifying the trypanosome in man will in the course of time prove of the greatest benefit to humanity and will be a lasting memorial to his skill and his self sacrificing devotion in the cause of scientific research in the tropics. The school, together with the whole

of the scientific world, were confidently looking forward to a long period of usefulness, of which Dr. Dutton's short but brilliant career held out every promise. Apart from the loss to science they feel deeply the loss to themselves by the removal from their midst of his bright and enthusiastic personality.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the second examination of the Board at the April quarterly meeting of the examiners in the subjects indicated:—

Anatomy and Physiology.—William Arthur Alexander, B.A. Camb., Cambridge University; Charles Henry Fairbank Atkinson, Charing Cross Hospital; Charles James Aveling, London Hospital; Bertram Freud Bartlett, University College, London; Alfred William Bevis, St. Mary's Hospital; Robert Stanley Capon, Liverpool University; Howard Bernard Carter and Thomas Evans, Guy's Hospital; James Aitken Clark, William Deane, [illegible] s's Hospital; Mohan Nath [illegible] ay, Grant Medical College, [illegible] King's College, London; [illegible] John Maximilian Hammond, [illegible] St. Bartholomew's Hospital; [illegible] .S., St. Bartholomew's Hospital; Arthur Toase Jackson, Robert Henry Hatten Jolly, and Thomas William Jones, Charing Cross Hospital; Arthur Reginald Hardy, Manchester University; John Edward Lionel Johnston, St. Mary's Hospital; Robert John Jones, St. Mungo's College, Glasgow; George Frederick Jotham, Birmingham University; Percy Lang and Alfred Miles, St. Bartholomew's Hospital; Arthur Norman Leeming, Guy's Hospital; Oswald William McSheehy and Max Herschel Edward Richard Montesole, St. Thomas's Hospital; Malcomson Knox Nelson, Queen's College, Belfast, and Guy's Hospital; Donald North, Leeds University; Herbert Edward Perkins and Cyril Macdonald Plumptree, Guy's Hospital; William Joseph Petty, William Edgar Roberts, and Alfred Samuel, University College, Cardiff; Edward John Joseph Quirk, Charing Cross Hospital; Percy Charles Raiment, and James Stanley Robertson, London Hospital; Rowland Waters Rix and Hubert Alan Hirst Robson, St. Thomas's Hospital; Arthur Frederick Sanderson, St. Thomas's Hospital; Francis Charles Searle, St. Bartholomew's Hospital; Reuben Shacksnovis, B.Sc. Vict., Leeds University; Edward Philip Stibbe, and Washington Everitt Wilks, Charing Cross Hospital; Charles Henry Shorney Webb, Middlesex Hospital; and Henry Adrian Fitzroy Wilson, St. Thomas's Hospital.

UNIVERSITY OF OXFORD.—The degree days for the ensuing terms are as follows:—In Easter term: Thursday, May 4th, and Thursday, May 25th. In Trinity term: Thursday, June 22nd, Thursday, June 29th, and Saturday, July 8th. The following have received the degree of Doctor of Medicine:—

Owen William Richards, New College; and Oscar Hildesheim, Magdalen College.

Examinations for scholarships and exhibitions in natural science are announced as follows: May 2nd, Merton College and New College; and July 4th, Brasenose College.

UNIVERSITY OF CAMBRIDGE.—The following candidates who have passed both parts of the examination in sanitary science have received the University Diploma in Public Health:—

D. G. Advani, R. Ahern, C. A. Bentley, I. D. Cameron, C. J. Coleman, J. W. Cornwall, T. S. Elliot, H. B. Fawcus, C. Fisher, T. B. Heggs, A. E. Jones, H. G. Jones, E. W. Routley, A. M. Simpson, J. B. Thackwell, and D. B. Waters.

At a Congregation held on April 27th the following degrees were conferred:—

Doctor of Medicine.—S. P. Pollard, Caius; and W. L. H. Duckworth, Jesus.
Bachelor of Medicine.—F. W. M. Palmer, Jesus.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on April 29th the following degrees and diplomas were conferred:—

Doctor in Medicine.—Anthony Bourchier Bradford, M.B., B.S. Durh.; Annie Tombleson Brunyate, M.B., B.S. Durh.; John Wilfrid Caton, M.B., B.S. Durh.; Thomas Morrison Clayton, M.B., B.S., B.Hy., D.P.H. Durh.; Flora Murray, M.B., B.S. Durh.; Alfred Henry Proctor, M.B., M.S. Durh.; Oswin Shields, M.B. Durh.; and Thomas Christoffel Visser, M.B., B.S. Durh. (*in absentia*).

Doctor in Medicine for Practitioners of 15 years' standing.—James Kynaston Couch, M.R.C.S., L.R.C.P.; Louis Demetriadi, F.R.C.S.E., L.K.Q.C.P. Irel., L.F.P.S. Glasg., D.P.H.; Herbert Edward Deane, M.R.C.S., L.S.A.; Frederick William Lewitt, M.R.C.S., L.R.C.P.; John Alfred Ward, M.R.C.S., L.R.C.P., L.S.A.; and Francis Henry Weekes, M.R.C.S., L.S.A.

Bachelor in Medicine (M.B.).—Dudley Thomas Birt and James Alexander Bennett, College of Medicine, Newcastle-upon-Tyne; John Frederick Bridge, Birmingham University; William Henry Hugh Croudace and Lillie Johnson, B.Sc., College of Medicine, Newcastle-upon-Tyne; Frederick William Kemp, St. Bartholomew's Hospital; Bernard Warner Lacey, Guy's Hospital; Thomas William Maddison, College of Medicine, Newcastle-upon-Tyne; Aurelius Victor Maybury, M.R.C.S., L.R.C.P., Guy's Hospital; Andrew Banks Raffle and Charles Duncan Relton, College of Medicine, Newcastle-upon-Tyne; Leslie Martin Rosten, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Olga Alberta Schiele, London School of Medicine for Women and College of Medicine, Newcastle-upon-Tyne; Alan Ayre Smith, M.R.C.S., L.R.C.P., Guy's Hospital; and Ernest Charles Young, St. Mary's Hospital.

Bachelor in Surgery (B.S.).—Dudley Thomas Birt, James Alexander Bennett, William Henry Hugh Croudace, and Lillie Johnson, B.Sc., College of Medicine, Newcastle-upon-Tyne; Frederick William [illegible] Hospital; Bernard Warner Lacey, Guy's [illegible] m Maddison, College of Medicine, New- [illegible] ius Victor Maybury, M.R.C.S., L.R.C.P., [illegible] Banks Raffle and Charles Duncan Relton, College of Medicine, Newcastle-upon-Tyne; Leslie Martin Rosten, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Olga Alberta Schiele, London School of Medicine for Women and College of Medicine, Newcastle-upon-Tyne; Alan Ayre Smith, M.R.C.S., L.R.C.P., Guy's Hospital; and Frederick Spicer, M.D. Durh., M.R.C.S.

Bachelor of Hygiene (B.Hy.). [illegible] & S. Madras, D.P.H. Cantab [illegible]

Diploma in Public Health [illegible] M.R.C.S., L.R.C.P., John Cha[illegible] James Maclanachan Ferguson, L.R.C.P. & S. Edin.

MEDICAL MAGISTRATE.—Mr. William Jackson, M.D. Brux., D.P.H. Cantab., L.R.C.P. Edin., barrister-at-law, has been placed upon the commission of the peace for the borough of Nelson, Lancashire.

VITAL STATISTICS OF ST. VINCENT.—Mr. E. J. Cameron, Administrator of the Island of St. Vincent, in his report on the colony for the year 1904 quotes the following figures. The population at the 1891 census was 41,054. By the estimate of the Registrar-General the population at March 31st, 1904, was 48,424. The births registered in 1903–04 were 1518—760 male and 758 female—as against 1551 in 1902. Of these 836, or 55·07 per cent., were illegitimate. Stillbirths were 119, 42 legitimate and 77 illegitimate, the figures being, curiously enough, all precisely the same as for the year 1902. Marriages appear to be appreciably on the increase, there having been 66 in the first quarter of 1903, against 30 in the similar period of 1902, and 241 in the year 1903-04, as against 226 in the calendar year 1902. The total registered deaths were 875, being 18·07 per 1000 of the estimated population. The infant mortality (infants under one year exclusive of stillbirths) was 222, being about 25 per cent. of the whole. If the death-rate may be taken as an index of the public health then 1903–04 was an exceptionally healthy year, the number of deaths registered being 52 below the average of the preceding years, which was 927. Ankylostoma, syphilis, and intestinal parasites are the three great evils with which the medical staff have to contend. Malaria was severe in certain localities and there was also an epidemic of whooping-cough. The peculiar form of small-pox, to which the hybrid designation of "varioloid varicella" was given, was introduced from Trinidad, but fortunately was prevented from spreading. After an experience of 23 years, which embraces every single one of the British insular colonies in the West Indies and several foreign ones, Mr. Cameron is inclined to set down St. Vincent as the healthiest and pleasantest in climate of all for the European dweller who has to spend two or three years at a stretch in one place without a break. There is nothing special under the head of sanitation to call attention to. In the villages of the peasantry the ideas and methods in sanitary matters are elementary in the extreme. In the towns things are passable but could be much improved if there were money to lay out. On the whole, however, there are no glaring evils. The number of patients treated at the Colonial Hospital during the year 1903–04 was 1014, of whom 897 were discharged cured or relieved, 15 were discharged not improved, 50 died, and 52 remained in hospital. The daily average was 61·38. The admission figure for 1903–04 was 967, the highest yet recorded. It included 239 cases of ankylostoma. There were also 266 operations performed, exclusive of teeth extractions, catheterisations, &c. A portion of the old military barracks at Fort Charlotte is set aside for temporary detention of lunatics prior to their removal to the asylum at Grenada. There were 17 cases under treatment during the year (nine being new admissions), of whom two were discharged cured, two died, and six were transferred to the asylum at Grenada. The total number of St. Vincent lunatics under care there was 32. The number of inmates of the leper asylum on March 31st, 1903, was 13; three fresh cases were admitted during the year 1903–04. The medical officer who has this institution under his care writes: "The inmates are steadily decreasing in number. Two who were merely syphilitic and had recovered were discharged. One case of anæsthetic leprosy who had recovered was allowed to go home and one case of doubtful diagnosis was also allowed to go. There is no compulsory segregation nor is any attempt made to collect all the lepers of the colony in an asylum. It will shortly be a matter for consideration whether it be worth while continuing this institution. It will be cheaper to afford outdoor help to the few lepers now there and close the building."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

A Small-pox Return.

SIR JOHN BATTY TUKE intends to ask next week for a return showing each port or other sanitary district in England and Wales exclusive of any district wholly or partly in London) in respect of which during the year ended March 25th, 1905, cases of small-pox have been reported to the Local Government Board; the number of such cases; and also, where the number reported has exceeded 100, the estimated amount of the expenditure incurred by the sanitary authority in consequence of the occurrence of such cases.

BOND, FRANCIS T., M.D. Lond, M.R.C.S., F.R.S. Edin, has be
appointed Medical Officer of Health of the Chippenham Urb

t., M.R.C.S., L.R.C.P. Lon
ical Superintendent to t
W.
n appointed Surgeon to t
Bolingbroke Hospital, Wan

was necessary. I was much surprised that my request was not granted. I attended the subsequent inquiry on April 18th and beg to append the evidence taken in court.

"The mother: The child was vomiting like water and phlegm. I put him to bed; he became light-headed. On Friday morning I called in Dr. Kennard who gave no hope; he died at 1 P.M. He has not met with any injury as far as I know, but has suffered from cough. [No evidence of duration of cough was given in the coroner's court or elsewhere.—D. F. K.] During night deceased groaned as if in pain. He was at school on Thursday and was playing in the court until 8.30 P.M.

Douglas Fredk. Kennard, L.R.C.P., L.R.C.S. Edin., 139, Hanbury-street, N.E., deposed to . deceased child dying and he died an hour later. as unconscious when I saw him, one pupil being contracted, the other dilated.

The Coroner: And what do you say is the probable cause of death?—Witness: *I have no idea of the cause of death, it might be due to a* blow or anything.

The Coroner: You have come here at the expense of £1 1s. to the county to assist me and you say that it may be a blow. Did you see any mark?—Witness: No.

The Coroner: *Do you generally find wheezing arise from a blow?*—Witness: No.

The Coroner: Then it is simply a reckless statement on your part; very well, you cannot assist me, so I must do without your assistance.

The Coroner (to Jury): I suggest that the child was subject to bronchitis, then got a cold on the lungs, and congestion of lungs was *set up; if you think deceased was poisoned or met with an injury* we will have a pathologist from the London Hospital to make a fuller examination; but if you are satisfied and say that you don't think it necessary you may return a verdict. I don't think it necessary to have the poor child cut up for idle curiosity. I suggest to you that the child died of pneumonia.

The jury adopted the coroner's suggestion and a verdict to that effect was recorded."

I wish to add, Sirs, that I have obtained the opinion of several of my local *confrères*, who are unanimous in condemning the coroner's action, and I have had the pleasure of having a conference *re* the above case with Mr. A. J. Pepper, who is of opinion that a post mortem examination should have been granted to ascertain the cause of death, which, I may further add, in my opinion was certainly, at least there was no evidence whatever to prove so, not pneumonia.

I *cannot reconcile* the *fact of* a schoolboy regularly attending his school and in his usual health up to the eve of the day of his death dying from pneumonia in the manner Mr. Wynne E. Baxter suggests.

I am, Sirs, yours faithfully,
April 29th, 1905. DOUGLAS F. KENNARD.

THE TREATMENT OF CHRONIC ALCOHOLISM.

To the Editors of THE LANCET.

SIRS,—I should be very glad if any of your readers could give me specific information as to the efficacy, as well as particulars, of a treatment of chronic alcoholism by means of hypodermic injection of atropine. I am, Sirs, yours faithfully,

C. F. TUCKER, M.B., Ch.B. Melb.
Beeac, Victoria, March 27th, 1905.

BREAKING UP THE STREETS.

THE following paragraph, which appeared in a recent issue of our contemporary, the *Westminster Gazette*, shows that the Paris police have evidently grasped the inner meaning of breaking up a street in a manner which is as yet unknown to our slower Anglo-Saxon mental working:—

> A QUAINT DELUSION IN PARIS.
>
> About 5 o'clock yesterday afternoon four men might have been seen taking up the paving-stones and making "soundings" around the Panthéon. The gendarmes were communicated with, and on arrival inquired what the workers were doing. They replied that they were endeavouring to find a spring to furnish water for the transformation of the dome of the Panthéon into a fountain. The officers tactfully offered to send helpers and promptly four policemen in disguise came to help the amateur engineers who were taken by the gendarmes to the infirmary at the depôt; they had recently escaped from a lunatic asylum.

THE RULE OF THE ROAD.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Observer" in his letter upon Manners in the London Streets advocates the adoption of a uniform rule of the road—i.e., that both foot passengers and vehicles should keep to the same side, which for some unknown reason he declares should be the left, although he has mentioned that in France the right is chosen. May I point out that whatever may be the origin of the British custom of walking on the right and riding or driving on the left, it has this consideration to recommend it. The pedestrian, if the rule is observed where there is no footpath, is always on the other side of the road to that occupied by vehicles and horses (including motor-cars and bicycles) coming upon him from behind. He can keep an eye on those which will pass near him and avoid them if necessary *without* turning his head in order to see how closely they intend to "shave" him. I am, Sirs, yours faithfully,

CONSERVATIVE.

A WARNING POISON BOTTLE.

Messrs. Kenneth Brown and Co., a firm of solicitors, have submi to us a specially shaped bottle invented by one of their clients wit view to minimise the danger of poisonous liniments and the being mistaken for internal medicines. The bottle is longitudin constricted on both sides, with the result that it closely resem the well-known pinched-in "Black Forest" bottles which commonly used for whisky and its shape will certainly rende impossible for anybody picking it up in the dark to mistake it an ordinary medicine bottle. The idea seems to be a good one no device of this kind can be an absolutely certain guard aga occasional gross carelessness.

AN OCTOGENARIAN MEDICAL STUDENT.

IT is announced in the *Novosti* that the Russian Minister of Educat has authorised the admission to examination before the med examination committee of the Kieff University of St. Vladimir the degree of doctor, of Phedor Maratzevitch, who is over years of age. According to the *Kieff Gazette*, at the end of "fifties," Maratzevitch attended the lectures at the University Kharkoff and then he entered the University of St. Vladimir in year 1863, being then over 40 years of age, but he did not obtai degree.

◆

J. H.—1. A circular of the nature described can be sent round by A his own patients. He must be careful to send it only to patie whose names appear on his books, and as far as possible it is advisa to substitute a personal introduction. 2. This is a purely *leg* question. The conditions of partnership are decided by the gener law of the land as modified by the special conditions of t agreement.

Geologist.—Without knowing the exact purpose for which our corre spondent requires a text-book on elementary hygiene it is difficult t recommend any particular work. Is the book required for consult tion or for examination purposes, and if the latter what examinati has the student in his mind?

F.R.C.S.Edin.—It is not easy to answer the questions categorically b we will give them further consideration. It seems to us that t medical men both acted quite properly in every respect.

Medical Diary for the ensuing Week

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M. EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private informa- [illegible] *d addresses of* [illegible]

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

A Lecture

ON

A CASE OF CONCEALED MENSTRUATION; WITH REMARKS ON TREATMENT.

Delivered at the Medical Graduates' College and Polyclinic on Feb. 22nd, 1905,

BY PETER HORROCKS, M.D. LOND., F.R.C.P. LOND.,
SENIOR OBSTETRIC PHYSICIAN TO, AND LECTURER ON MIDWIFERY AND DISEASES OF WOMEN AT, GUY'S HOSPITAL.

GENTLEMEN,—The subject of to-day's lecture was selected in order to bring before your notice in as prominent a manner as possible a method of treatment which very nearly cost the life of a patient, which has, indeed, in the past proved fatal in many cases, and which if persisted in will result in other deaths. Before reading to you the notes of the case it may be as well to remind you briefly of the various conditions that obtain in different cases, or in successive stages of the same case, in concealed menstruation.

A so-called imperforate hymen consists in most cases of a hymen in which the opening is filled in by a membrane. In such a case when the menses first appear they flow into the vagina and not being able to escape a portion gets absorbed before the next monthly flow and a portion remains. As time goes on this remainder grows until the vagina is distended with a dark treacly fluid which generally remains aseptic. This is the condition known as hæmatocolpos, and is practically free from danger no matter how it is relieved. But if the imperforate hymen is strong enough not to yield and the concealed menstruation continues then the uterus gradually gets distended and so a condition of hæmatometra is superadded, and in this state the uterine and vaginal cavities form one large common cavity concave above and below and more or less cylindrical in between. If unrelieved the Fallopian tubes become distended and so a hæmatosalpinx results. Some believe that the Fallopian tubes may become distended independently of regurgitation from the uterine cavity, the blood in that case coming from the lining of the tubes themselves, but whether that is so or not it is quite certain that if the blood in the uterus becomes septic it, as a rule, contaminates that in the tube or tubes. Finally the blood may escape into the peritoneal cavity, causing a hæmatocele, or burst into the broad ligament, causing a hæmatoma.

Concealed menstruation must be looked upon as a rare condition. Probably imperforate hymen is the commonest cause of it but it may result from congenital or acquired atresia of any part of the parturient canal, from the os internum of the uterus, downwards. For example, congenital atresia of the vagina in its lower third is, perhaps, the next most common condition met with and complete closure, from cicatricial contraction, has followed sloughing of the parts about the cervix uteri, after severe labours. So long as a patient with concealed menstruation remains unrelieved she is in danger of, firstly, septic infection and secondly, of rupture of some portion of the distended parts—namely, tubes, uterus, or vagina. Such rupture might cause serious, possibly fatal, hæmorrhage or it migh[illegible] without, which would cause [illegible] of the retained fluid. Again, [illegible] concealed menstruation, the very same two risks are run—septic infection and rupture. But the former is a far greater and commoner risk than the latter. Indeed, rupture is almost unknown following upon treatment, whereas sepsis and death have resulted in many cases.

Having thus sketched out briefly the various conditions that may be met with, allow me to read you the notes of a case which occurred during the last few months.

The patient, a girl, 15 years of age, began to have pains about the loins and lower parts of the abdomen which suggested the onset of menstrual life. No sign of blood made its appearance but as the pains recurred about once a month the mother of the girl adopted various measures of treatment, such as sitting the child over hot water, hoping to assist the flow. The girl felt quite well in between these attacks, but after nine or ten months, as there was still no flow, the mother called in Dr. X. and subsequently his partner, Dr. Y. They examined the girl, discovered a bulging imperforate hymen, and correctly diagnosed concealed menstruation. They consulted a modern text-book with regard to the treatment of so rare a case, where they read that the retained menses should be let out gradually by making a tiny puncture through the imperforate hymen. The book spoke of the danger of letting out the fluid suddenly—namely, contraction of the uterus with regurgitation along the tubes of retained menses, into the peritoneal cavity. So on Nov. 22nd, 1904, they applied some cocaine and with antiseptic precautions made a tiny puncture through the [illegible] treacly, but non-[illegible] to escape until, [illegible] came away during the following few days. Before the puncture was made the girl had been quite healthy and well. But in two or three days she began to get ill and feverish and the still flowing menses became offensive. Obviously they had become septic and were decomposed and the girl was in a sapræmic condition. So a week after the first puncture—namely, on Nov. 29th—cocaine was again applied to the hymen and with antiseptic precautions a free incision was made and the uterus and vagina were washed out with sterilised water, the contents being very foul. During the introduction of the nozzle of the syringe it was discovered that the uterus and vagina formed practically one cavity, so that it was not easy to find any part of the wall where one could say the vagina ended and the uterus began. In other words, it was quite clear that it was at least a case of hæmatocolpos and hæmatometra. For a short time the patient seemed to be a little better but she rapidly grew worse after that, with signs of septic peritonitis.

Receivin[illegible] Dr. Y., I [illegible] was quite [illegible], although there was then no offensive discharge because douches of tinctura iodi, one drachm to the pint, had been given frequently. The pulse was over 120, the temperature was 101° F., the face was pinched and anxious-looking, the tongue was dry and brown, and the abdomen was distended and tender all over, but more especially in the lower half. Nothing but an abdominal section offered any hope of recovery and one could not promise that even this would assuredly save the patient's life. Fortunately, her parents were sensible people, and whilst consenting to have the operation done they, more especially the mother, wished to have it done at home. The objection to this was that the surroundings were not favourable to an abdominal section of that kind. The advantages of having it done in a surgical home where we could have a brilliant light right over the table to illuminate the area of operation, a table arranged so as to put the patient in the Trendelenburg position if need be, together with all modern devices for the attainment of as perfect an asepsis as possible and with skilled nurses accustomed to abdominal section cases, quite outweighed the slight inconvenience of the removal. It was said that the patient herself would object but on placing it before her she consented on one condition—namely, that she should retain the services of her nurse, to whom she had become greatly attached—a thoroughly trained nurse who proved to be most efficient and trustworthy.

The patient arrived at the nursing home about three hours after I first saw her and in the meantime everything had been prepared for immediate operation. She was first placed in the lithotomy position and the vulva was shaved and made aseptic as far as possible. The opening which had been made in the hymen was found to be rather small and so it was enlarged by incising the hymen on each side to its base. On vaginal examination it was found that it was possible to pass the finger through the patent cervical canal and that the cervix uteri had become differentiated from the vagina. But the lips of the os uteri were flush with the vagina all round; in other words, there were no fornices. One could feel, also, that there was something in the region of the pou[illegible] but only a [illegible] of the uter[illegible] lotion, 1 in 500, and finally they were both packed with iodoform gauze wrung out in the same lotion. She was next placed in the dorsal position for laparotomy.

As soon as the abdomen was opened by a median incision an exceedingly foul, watery fluid escaped and on dipping the fingers into the pelvic cavity stinking pus welled forth through the opening. A mass as large as a man's fist was felt lying behind and to the right of the uterus and on lifting it out, which was easily done as there were no adhesions, it proved to be the right Fallopian tube greatly distended, which will now be passed round for your inspection. This was removed after transfixing and ligaturing the broad ligament in the usual way. Before proceeding further the pelvic cavity was washed out with saline solution (two drachms to the pint), many quarts being used. The stench was almost overpowering and as several sloughy-looking pieces, probably of decomposing clot, escaped, some large jugsful of the saline fluid were poured into the pelvic cavity so as to create a sudden and powerful flush of water. Lying on the back of the uterus, the bottom of the pelvis, and here and there on the intestines, there were large flakes of wash-leather-like lymph and the peritoneum generally was red and inflamed. Finding that more stinking fluid kept flowing down from amongst the intestines above it was determined to try the almost impossible task of cleaning the peritoneum generally, for it was a case of life or death and it seemed that the only chance for the poor girl was to get rid of as much as possible of this stinking stuff. With a Tait's metal tube fixed at the end of thick rubber tubing attached to the douche can, the whole of the contents of the abdomen, diaphragm, liver, spleen, kidneys, stomach, and bowels, were all thoroughly douched with saline fluid, many gallons of which were used at a temperature of 105° to 110° F. When at last the fluid came out sweet the left Fallopian tube was carefully inspected, and although it was swollen and inflamed on its peritoneal aspect and the fimbriæ were swollen, yet as no pus could be squeezed out by rubbing from the uterus towards the abdominal ostium it was determined to give the girl a chance of keeping this important organ. It was quite obvious that we must have drainage, the only question being whether to make an opening through Douglas's pouch and to drain per vaginam or to put in a Keith's glass tube and to drain through the abdominal wound. Not being quite sure as to the aseptic condition of the vaginal walls and Keith's glass tube being a quicker and simpler means I used one and sewed up the wound and got the patient back to bed as quickly as possible. The operation lasted over an hour altogether and the pulse was 140 at the finish. Coffee and brandy were administered in the form of enemata every four hours at first and afterwards every six hours. A morphine injection, one-third of a grain, was given subcutaneously the same night. Fluid was sucked out of the tube every half hour. On the next day the fluid drawn off by the syringe was foul again and also purulent. So a solution of sulphurous acid (50 per cent.) was used to syringe into the pelvic cavity through the glass tube, the fluid being at once sucked out again. As this caused so much burning the strength was reduced to one part of sulphurous acid to two of water. A glass syringe containing about two ounces was used and it was refilled two or three times at each syringing which was repeated about every half hour at first and then every hour. The patient's condition was extremely critical for a few days, but as she took and kept down a fair amount of milk and barley-water, besides retaining coffee and nutrient enemata, there was a little hope that she might possibly pull through.

On the sixth day the glass tube got pushed out a little and the lower end became blocked. Hence it was impossible to suck anything out and inasmuch as before the disturbance of the tube the fluid last drawn had been extremely foul and purulent one could not feel happy about the absence of fluid being a good omen. That the lower end of the tube was blocked became rapidly apparent by a rise of temperature and other evidences of septic absorption, such as quick pulse and dry tongue. The glass tube was turned round on its vertical axis and a probe was passed down to the bottom, very gently of course, but it was quite 24 hours before we succeeded in again reaching the stinking pus. At all events, when it was found and the syringing in of the sulphurous acid got at the septic parts the temperature again fell and the patient improved in every way. The abdomen was somewhat distended, especially at the lower part, and also hard all over, before the operation; and afterwards it became more distended still. But by means of repeatedly passing a rectal tube and by getting the bowels to act by various measures, such as cascara, soap-and-water enemata, turpentine enemata, and the like, we managed to keep it within bounds. On the ninth day she began to take a little solid food and this was gradually increased until she was able to eat well. On the fourteenth day the sulphurous acid lotion was given up and boric acid lotion was used instead. On the seventeenth day the glass tube was removed and an indiarubber tube was put in its place. This was itself replaced by a very narrow one on the twentieth day, and finally a little gauze drainage was employed. The cavity filled up with healthy granulations and the patient got up on the couch on the forty-fourth day. She went home on the fifty-ninth day practically well.

It seemed to me that considering how nearly this girl lost her life through a method of treatment which is known to be dangerous and which ought never nowadays to be adopted, and considering also that her life was saved when in an apparently hopeless condition, that it ought to be brought prominently before the profession in order that no similar mistakes may be made in the future. Concealed menstruation is not a condition often met with. A busy practitioner in a long professional life might not have in his practice more than one or two such cases. This was the very first case Dr. X. and Dr. Y. had ever had to treat and naturally they consulted a text-book on diseases of women which recommended the treatment by puncture. They were thus entirely misled and must be exonerated from all blame. Indeed, many text-books contain the same advice, some giving both methods of treatment—namely, a tiny puncture and a free incision. Scarcely any condemn utterly the plan of letting off a little at a time, although they point out the dangers of it.

But you must remember that some cases appear to do perfectly well when a small puncture is made. Why is that? My reply is that the cases which do well are probably cases of hæmatocolpos only. The danger of letting out the fluid slowly is practically *nil* when the vagina alone is distended. For even if the contents become septic, there is not so large a quantity and the vagina is not so powerful in its contractions as the uterus and it would burst the fragile hymen or its own walls more readily than drive its contents into the uterine cavity. Where, however, there is hæmatometra in addition to hæmatocolpos the danger of making a tiny puncture is very great and it ought never to be done. You all know that the surest means we possess for bringing on uterine contractions in pregnancy is to rupture the membranes. No other method known is to be compared with this for rapidity and certainty. The puncture of the membranes lets out some of the liquor amnii and thus removes the hydrostatic pressure exerted on to the uterine walls. There is an immediate shrinkage of the uterus, followed by more active contraction, resulting in the majority of cases in definite expulsive pains which end in miscarriage or labour according to the time of gestation. The exact physiology of this provocation of uterine contractions has not been settled but precisely the same condition obtains in a combined hæmatocolpos and hæmatometra. Hence, to puncture the imperforate hymen is the very surest way to provoke uterine contractions. These follow one another in ever-increasing volume and force and frequency until, as there is no sufficient outlet through the tiny puncture, the retained menses get driven into the generally patent Fallopian tubes and through them into the peritoneal cavity. If, as in this case, the menses have become septic, which is almost sure to happen after a few days no matter how antiseptically and aseptically the puncture be made, peritonitis ensues and, so far as I am aware, this is the first instance on record where when this has happened the patient's life has been saved by abdominal section.

It is nearly 20 years ago that I lost a case myself through sepsis following puncture of a distended hymen. A post-mortem examination revealed a peritonitis set up by septic menses driven into the peritoneal cavity along the Fallopian tubes. There and then I determined never to adopt that treatment again but to make a free incision and to wash out the whole of the contents from above downwards and so give them no time to decompose. I have operated on a fair number of cases since but have never lost one. The essential factor has been the free incision and the rapid washing out, but during the 20 years, of course, various improvements have been made in regard to asepsis. The fully developed method may be described as follows. The patient may be anæsthetised or not, as the case may be, but in all the cases I have treated an anæsthetic has been given. The vulva is rendered aseptic as far as possible, especially the generally bulging imperforate hymen. After shaving and washing with soap and water and then by a 2 per cent. solution of lysol it is a good plan to apply a piece of sterilised gauze or other material soaked in 1 in 1000 perchloride of mercury or an equivalent germicide to the bulging hymen, leaving it to soak for not less than two minutes. A two-quart douche can is filled with either a mild antiseptic lotion or with boiled water, to which may be added one or two teaspoonsfuls of common salt to the pint. It should [illegible] feet above the [illegible] delivery pipe by [illegible] inch in diameter. The delivery tube should be from 12 to 14 inches in length and should have a good wide bore opening at the end. The old-fashioned gum-elastic tubes which were formerly used for the intra-uterine injection of perchloride of iron in cases of post-partum hæmorrhage are first rate. They are preferable to nozzles having small openings at the sides. What you want here is a good stream to flush out the cavity quickly and there is no risk of air getting into the veins, for there are no open veins for it to get into. Moreover, you practically avoid air getting in by turning the tap and allowing the fluid to run out a little before introduction. The temperature of the fluid should be about 105° F. As soon as everything is ready a good incision is made right across the bulging hymen. This can be done by a knife or cautery or scissors. It is a good plan to seize the lower cut margins with catch forceps and to let these hang down; they stop bleeding and keep the vaginal orifice open. The nozzle of the douche apparatus is then rapidly passed through the incision to the top of the uterus and the two quarts of solution are allowed to flow rapidly and with force so as to wash the whole contents from above downwards, out through the opening made. If the returning fluid be still red, as it probably will, when the two quarts are nearly exhausted the douche should be filled again with more saline solution, a plentiful supply of which should be ready. This washing out should be carried on until the returning fluid is clear. The uterine and vaginal cavities can now be packed with gauze, aseptic or antiseptic, but of recent years I have contented myself with passing into the vagina only a little iodoform gauze wrung out in formalin 1 in 750. This can be left in for 48 hours and then removed and a douche of saline fluid or boric acid lotion can be given and a little fresh gauze tucked into the vagina. This gauze acts as an antiseptic and aseptic cork preventing ingress of germs from without as well as acting as a drain. Since adopting this method I have never had a death and indeed never any trouble; the patient has usually made an excellent recovery without rise of temperature though generally with some pains due to uterine contractions.

Of course, when the bulging hymen is incised there is an immediate flow of the viscid dark fluid and doubtless there is an immediate shrinkage of the distended cavity; but the incision is so large that the pressure brought to bear by this shrinkage drives the menses through this opening easily, thus preventing any danger of its being driven along the Fallopian tubes where resistance is much greater. It might be argued by some, "Why not make a free incision simply without washing out?" My own opinion is that such a method might succeed every time. Certainly it would be far superior to merely puncturing. But obviously it would take some time for the uterus and vagina to expel *all* their contents and as these contents are liable to easy infection and decomposition it is better to get rid of them as rapidly as possible so that the uterine and vaginal cavities contain practically nothing that is capable of decomposition. Some prefer to wash out more gradually and more gently on the supposition that a too rapid emptying of the uterine [illegible] ouble through uterine contractic [illegible] aused by past perimetritis; such [illegible] and if trouble is going to arise on account of uterine contractions it will not be prevented by a slow, in preference to a rapid, washing out. The advantage of the rapid method is that all the retained menses are got rid of before there is time for infection and decomposition and before there is time for the strong uterine contractions to commence.

If, however, it should ever come before you to have to deal with a case of acute peritonitis set up by regurgitation of septic fluid along the Fallopian tubes into the peritoneal cavity, the only chance for the patient is abdominal section, removal of the offending blood and, if need be, one or both tubes, and a thorough washing out of the peritoneal cavity. Anyone who has tried to wash out the abdominal cavity thoroughly knows what an extremely difficult thing it is. Pools of stinking pus seem to exist here and there amongst the small intestines after one has apparently got the whole cavity clean. In this particular case, knowing that the more thoroughly the purulent and most offensive fluid was got rid of the more likely the patient would be able to pull through, I set deliberately to work to accomplish the task of cleaning the peritoneum. With this purpose the nozzle of the tube was guided up between the liver and the diaphragm, between the spleen and the diaphragm, round and about both kidneys, and over the stomach and intestines, separating the coils of small intestine here, there, and as far as possible everywhere, in order to direct a rapidly flowing stream of saline solution upon every part of the abdominal cavity. Of course the pelvic contents received the greatest amount of douching and by the time this had been finished there was no pus in, and no offensive odour from, the out-flowing water.

During the operation I was in doubt whether it would be best to remove the left tube as well as the right but as it was only swollen and contained no pus apparently it was decided to leave it. Another point was whether it would be better to make an opening through Douglas's pouch and so to drain into the vagina. Possibly that would have been the best plan but drainage through the abdominal wound by means of a Keith's glass tube was decided upon partly because it could be done much more rapidly and the patient's condition was serious, rendering every minute of value, and partly because the vaginal walls were themselves probably far from aseptic. When the glass tube became blocked and signs of sepsis arose it was felt that perhaps it would have been better to have had a drain through the vaginal roof. And, indeed, had we been unable to get the [illegible] been made [illegible] Happily, [illegible] so drainage was re-established. The patient's life was saved and that must be remembered in any future case where the question of abdominal or vaginal drainage is discussed. All who were present at the operation thought that it was impossible for the girl to recover. The whole peritoneal cavity was affected by peritonitis and the stinking purulent fluid bathed the entire abdominal contents. But it must be admitted that an infection accompanied by fœtor is less virulent as a rule than some infections which are quite free from bad odour. Take for example puerperal septic infections. That form in which the lochia are offensive is nearly always recovered from, whereas the fatal cases have as a striking clinical feature scanty sweet lochia.

Again, in suppurative fatal peritonitis there is practically, as a rule at all events, no fœtor present when the abdomen is opened. Hence one felt in this case that if the whole or at all events the bulk of the septic stinking fluid could be washed away the vital forces of the patient might be able to battle successfully with the remainder. And happily this proved to be the case. All text-books tell you of the dangers of letting out retained menses—namely, rupture of the Fallopian tubes and sepsis. Some recommend a preliminary abdominal section to find out the condition of the tubes, a method of procedure with which I disagree. But since adopting the method of free incision followed by free washing out of the whole uterine and vaginal cavities I have had no bad result, so that one may say that practically the element of danger from sepsis can be eliminated. Certainly I know of no method for preventing sepsis if a tiny opening only be made in the atresic portion.

As regards the danger of rupture of an already distended tube it seems to me greatly to be exaggerated. Personally I have never come across such a case, and even if it did rupture the contents are nearly always aseptic and would lead therefore to no dangerous peritonitis. And as to hæmorrhage from the ruptured walls of the tube it would be slight and not enormous as in the case of ruptured tubal gestation because, of course, there would be no chorionic villi or placenta. So far as I have been able to refer to text-books on diseases of women not one tells you what to do in case a septic peritonitis supervenes upon the treatment of a case of concealed menstruation by puncture or incision of the atresic hymen or other part. It almost appears as if it were considered a hopeless and an irremediable state for which there was no remedy. I trust that the publication of this case may lead in the first place to an abandonment of the treatment by puncture, and in the second place to the adoption of the treatment by free incision and washing out, and finally in cases where peritonitis supervenes to an immediate laparotomy with thorough cleansing and drainage.

The following report has been drawn up for me by Mr. H. T. Hicks, obstetric registrar and tutor at Guy's Hospital. "The specimen consists of the right Fallopian tube and its corresponding ovary, covered and bound together with firm but recent adhesion. The uterine end of the tube is free and from this point the tube curves outwards and downwards and embraces the enlarged ovary in the concavity of its curve. The ovary is uneven on the surface and covered with a thick layer of lymph and in its interior is a small abscess cavity which contained thick pus. The walls of the tube are much thickened and in a condition of interstitial salpingitis while the lumen of the tube is dilated and tortuous. The mucous membrane is œdematous and in the recent state the tube contained a dark chocolate-coloured material mixed with pus resembling breaking-down blood clot. The dilated tube has been infected by an acute septic organism which, passing quickly along to the fimbriated end, has secondarily infected the ovary, forming a small abscess in its interior and peritonitis around. It is interesting to note the great thickening of the muscular coat of the tube as well as the peritoneal coat. The sections show that both the muscle and the mucous membrane are in a condition of acute inflammation with much small-cell infiltration."

The Lumleian Lectures

ON

NUTRITION AND MALNUTRITION.

Delivered before the Royal College of Physicians of London on March 28th and 30th and April 4th, 1905,

BY W. H. ALLCHIN, M.D. LOND., F.R.S. EDIN.,

FELLOW AND CENSOR OF THE COLLEGE; SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

LECTURE II. *(concluded).*[1]

Delivered on March 28th.

THE RÔLE OF OXYGEN IN TISSUE METABOLISM.

IN the course of these complicated changes, both anabolic and katabolic, the part played by oxygen is necessarily of considerable importance. The problem was the subject of an interesting discussion introduced by Sir John Burdon Sanderson at the last meeting of the British Association for the Advancement of Science. That it is a potent factor in those changes which constitute the disintegration of such tissues as muscle and nerve-centre in connexion with the manifestation of their specific energies has long been a commonplace of physiology and the resulting products of oxidation, such as carbonic acid and water, were known to be proportionate to the work done. More recently it has come to be realised that oxygen plays an important part in the constructive phases of living matter, though precise information on the point is still to seek. So far, however, it appears that for the restitution of the living molecule after the disintegration attendant on its transition from an inactive to an active state oxygen is essential, "not as an oxidiser, but as a restorer of functional capacity." It is requisite that the element should become a part of the bioplasm—intramolecular—whereby the excitability of the tissue—muscle or nerve-centre—is increased, and the response to a suitable stimulus, as expressed by the disintegration of the living substance with liberation of energy, is induced. It is in this latter phase that the oxidising function of the oxygen comes into play, contrasting with its integrating function that renders possible the explosion. For this anabolic capability Sir John Burdon Sanderson suggests the term "oxygenation." Both in muscle and nerve-centre oxygen "acts as a predisposing, not as an exciting, cause of functional activity," though playing an active part in the katabolism of these tissues. In the case of excretory glands the rôle of oxygen appears to be different, for during the activity of these organs, so far as it has been observed in the salivary glands, the pancreas, and the kidney, there is a large increase in the intake of oxygen without the subsequent liberation of a corresponding amount of carbonic acid. It is then the anabolic action of the element which predominates in glands, as the katabolic does in muscle and nerve-centre. This difference in the part played by oxygen in the muscular and nerve tissues (grey matter) and in the secreting glands is further shown by the far greater production of heat which takes place in muscles and the greater the excretion of carbonic acid and water the greater the amount of muscular work. Although oxidation is so important a factor of katabolism it is not to be maintained that all the disintegration stages of the tissues (body-stuffs) are of this nature. The most complex—viz., the proteids—would seem to undergo certain preliminary decompositions in which oxygen plays no part; the splitting of these substances into a nitrogenous and a non-nitrogenous portion which may or may not be converted into sugar is an illustration. Some of the first products of proteid (muscle) metabolism are doubtless oxidised at a later stage, but, as already said, the katabolism of proteids is not one of complete combustion, as it is in the case of fats which are entirely converted into carbonic acid and water, and as is also the case with much of the carbohydrates unless the greater part of these substances are converted into fat before oxidation, a fraction only being involved in the proteid synthesis.

The tissues differ among themselves very much in the extent to which they are possessed of oxidative power, and Loeb has shown that the solubility of certain substances in the tissues is affected by the presence or absence of oxygen. How important this is in respect to the chemical interchanges between the cell and the materials presented to it will be obvious. There is much to show that the oxidations mostly take place in the nucleus of the living cell, which consequently becomes the chief seat of the syntheses that depend on these oxidations.[2]

THE PART PLAYED BY FERMENTS IN NUTRITION.

On looking over the whole series of changes, which I have merely indicated in outline, undergone by the ingesta from their first contact with the digestive secretions and their subsequent absorption to their final presentation to the living protoplasm and their assimilation and breaking down, we are led to recognise that these changes are, so far as they are known, exactly of the nature of well-known chemical processes. By hydrolysis or decomposition with previous hydration, by condensation, by oxidation, and by reduction, the various alterations in the food-stuffs are effected. Now these processes are precisely such as take place in our laboratories under experimental conditions and, indeed, many of the changes which I have described as occurring in the carbohydrates and fats and to some extent even in the proteids can be imitated at will in our flasks and test-tubes. But there is this great difference: that in our laboratory procedures to bring about these results strong acids or alkalies are required, a prolonged application of high temperatures or electric currents of great potentiality—conditions which obviously do not exist in the living animal or plant and that, indeed, would be destructive of it. On the other hand, in the simplest living cell, alike as in the highest form of existence, these same changes are effected rapidly and surely without any such powerful agencies. It is this marvellous accomplishment of chemical change, both synthetic and analytic, that characterises the living organism and that permits us to use with becoming understanding the expression "vital" as applied to them, though it may well be that such a term is provisional only and may not be taken to affirm an essential difference from those conditions which govern non-living matter. At the same time, it must be admitted that altogether fresh methods of chemico-physical action are disclosed by the investigation of the syntheses effected by the living organism and are not identical with those which take place in our laboratories.[3]

If now we seek for some explanation of the means by which the living thing effects these series of ascending and descending changes—the anabolic or constructive as well as the katabolic or destructive phases of metabolism—we find some clue in the conclusions drawn by numerous workers who have approached the problem from various points of view, starting not infrequently from previous knowledge that gave but little indication of the comprehensive and far-reaching results to which it has led. For many years it has been known that the activity of the several digestive secretions depends on the presence of bodies known as soluble ferments or enzymes, ptyalin, pepsin, trypsin, lipase, and the like, though but little had been ascertained as to the actual nature of these bodies, far less of their mode of action. Extended observation has demonstrated a widespread existence of these agents throughout the tissues, both animal and vegetable, and has shown not only that they are secreted from the cells in which they are formed and so enter into the specific secretions of the various secreting glands, but that they also may occur within the cells themselves and exert their peculiar activities in that situation—intracellular ferments. Among other consequences of this [illegible] which the yeast plant may be taken as a type, since from this organism a substance has been expressed that brings about all the changes in the carbohydrates which the living cells themselves produce. Great difficulty has been experienced in obtaining these bodies in even approximate purity and so far their real nature and mode of action are largely hypothetical. There seems, however, good reason to believe that in many cases they are of the nature of nucleo-proteids and are derived from the chromatin of the cell nuclei[4] but that between this substance and the enzyme are intermediate stages which are successively formed in the cell substance or cytoplasm, the immediate precursor of the ferment being known as zymogen. Their activity is largely conditioned by their environment; they are destroyed beyond certain limits of temperature and according to the degree of concentration of the medium in which they are will be in great measure the character of their results. The dependence of the formation of trypsin by the pancreas upon the circulation in the gland of a specific substance secretin and the further formation of trypsin from the zymogen by the action of another ferment (enterokinase) already referred to, seem to indicate some of the conditions of the origin and mode of action of these bodies concerning a knowledge of which we are but on the threshold. Their action is inhibited by the accumulation of the products of their activity, a removal of which permits a renewal of their effectiveness. Moreover, it appears to be pretty clear that for the due production of the specific changes which these enzymes induce the cells must be adequately supplied with suitable pabulum and what is of great importance the actual variety of ferment action depends very considerably upon the character of this pabulum, so that the same cell may give rise to different ferment actions. The adaptation of the gastric and pancreatic secretions to the particular requirements of different articles of diet previously alluded to serves to illustrate this statement. It was an investigation of this point in particular that led Croft Hill to the discovery of the reversibility of ferment action. The hydrolysis of starch into glucose by diastase has long been familiar to us and it was also known that long before the whole of the starch was converted the action came to an end if the resulting sugar were not removed; if now glucose be added to the mixture a reconstruction of starch takes place, the enzyme rebuilding the molecule it had previously split up. It is difficult to over-estimate the importance of this discovery, [illegible] and anabolic changes. Immersed in the several bioplastic constituents of the cell which are simultaneously undergoing both destructive and constructive changes, they bring about these decompositions and compositions determined in the direction of their activity by the relative proportion of the products to which they have given rise. Only when the breaking-up products (conveniently designated by Croft Hill kata-products) balance those of construction, or ana-products, is the activity of the cell in abeyance. "If either the ana-products or kata-products are removed from the sphere of action as fast as produced the other products will be entirely transformed. In this way the reversibility of ferment action is sufficient to explain the synthetic processes of life which may, and probably do, occur in stages, so that the ana products of one ferment are the kata-products of another, the final ana-products usually having a very low solubility."[5] The reversible action of lipase in the disintegration and integration of fats in the course of digestion and absorption which has been previously mentioned is an illustration of this point. From this it would be clear that the older notions that ferment action was solely in the direction of decomposition, of katabolism, must be amended and their efficiency as synthetic agents be recognised. And not only is this apparent in the manifestation of their reversible action but it is to be observed between different ferments which thus become, as it were, complementary to each other. Thus the glucoside amygdalin which is extracted from almonds may be broken up by one ferment into sugar, hydrocyanic acid, and the essence of bitter almonds, whilst another ferment obtained from yeast extract can reconstruct these substances into the original compound.

[2] [illegible] in Journal of Physiology, 1902, vol vii.

[3] [illegible] chemistry cannot, *as it at present stands*, be [illegible] into a direct negative of vitalism in any form [illegible] may, and probably will, be made possible in the future when our chemical *methods* have been made to approximate more closely to the vital *methods*" (The Chemical Synthesis of Vital Products, by Professor Meldola, F.R.S., 1904.)

Much has been said as to a constructive and destructive power of the living protoplasm as distinct from that of the enzymes which are formed from certain constituents of the protoplasm. The nature of these metabolic processes is in both cases the same and it seems probable, though it cannot be affirmed, that it is by these specialised portions of the living matter, these extremely complex bodies the enzymes, that the synthesis of the pabulum into the bioplasm is effected, and that so soon as this takes place by similar ferment action a decomposition is brought about "giving rise to many residues of various kinds, some of which are re-incorporated with new material into the molecules of the bioplasm, while others are broken down still further and ultimately eliminated." "Not only," continues Professor Reynolds Green,[6] "does the substance of the protoplasm itself undergo these decompositions, but different materials in the cells are involved in them and the residues of these are absorbed into, and incorporated with, the living substance in the same way as those which spring from its self-decomposition. We find that in many cells there is stored a reserve of nutritive material, not quite in a suitable state for immediate assimilation, but ready to form a nutritive pabulum when split up. Nor are such materials of use only as supplying nutritive material; by their decomposition a supply of energy is afforded to the protoplasm, of which it avails itself in carrying out constructive processes."

Many are the theories that have been advanced to explain the mode of action of these ferment bodies, but no one can be said to be completely satisfactory. The resemblance in their effects of setting up or accelerating chemical changes in substances, apparently without undergoing any material change or loss themselves, at once suggested a strong resemblance to similar activities long known to be possessed [illegible] atinum, gold, and silver when [illegible] Such power was [illegible] afforded by the term. A point of exceeding interest in reference to this is that many of the fermentations which we recognise as dependent on the action of enzymes, such as the oxidation of alcohol into acetic acid by the vinegar plant, may be effected by finely divided platinum, by which also cane sugar may be inverted, and, as lately shown by Neilson,[7] the hydrolysis and synthesis of fats, which in the body take place by the action of a ferment lipase, may also be brought about by mere contact with platinum black. So also such toxic agents as prussic acid will equally arrest the action of the cell-formed enzyme and of the metal. So wide is this ferment action, by which the various synthetic and analytic processes are performed, that within recent years a group of ferments has been recognised which are concerned in the transference of oxygen to the substance undergoing "fermentation." To these oxidising enzymes the name "oxidases" has been given and their presence has been detected in both animals and plants. Here, again, is seen a familiar chemical process which in our laboratories is effected by means of considerable heat or of such reagents as would be destructive of living tissues, carried out rapidly and quickly through the agency of these highly complex bodies which are present only in infinitesimal quantities. The first of these bodies to be detected now more than 20 years ago is one known as laccase, by which the lacquer varnish is produced; others appear to be concerned in causing the bouquet of wines; another takes part in the formation of indigo; and yet another, found in ripe olives, in the oxidation of the oil into oleic, acetic, and other acids. Recent observations by the committee of the British Association for the Advancement of Science previously referred to upon the localisation of these oxidases within the cells have shown that they are not components of the living framework of the cells but are dissolved in the fluids that bathe that framework and circulate in the cell spaces and cavities. And in view of the relation which these fluids have to the surrounding media it may be more correct to regard these bodies not as enzymes but rather as oxygen carriers very much as hæmoglobin is. The observation that certain animal tissues have reducing properties, such as being able to convert alkaline nitrates into nitrites, has suggested the possible existence of enzymes which could obtain the oxygen from somewhat stable compounds instead of from the atmosphere—in fact, reducing ferments.

---

[4] "This hypothesis," says Professor Reynolds Green, "is considerably strengthened by the observations of Macallum (Contributions to [illegible] till the time when the granules are fully formed."

[6] The Soluble Ferments and Fermentation, by Professor Reynolds Green, D.Sc., F.R.S., 1901, p. 363.

[7] American Handbook of Physiology, 1904.

Until quite recent years the function of a number of organs in the body known as the ductless glands, thyroid, parathyroids, thymus, adrenals, and pituitary body, was a subject of profound mystery. Chiefly as the result of clinical observation alterations in their structure were found to be associated with very widespread tissue change and general functional deterioration in various directions. Without wholly excluding the idea that these organs may be partly concerned in the withdrawal of some toxic products of tissue waste their influence on metabolism is attributed to the formation by them of internal secretions which are thrown into the blood or lymph circulation and so distributed to the body. The next step was to ascertain that this function of internal secretion is also possessed by some of the glands that furnish external secretions and possibly also by other structures with which glandular functions, as ordinarily understood, are not usually associated. That these organs, or some of them, exert a very important influence on the nutrition of the body is well known. The close association of the development of the reproductive glands with the growth of the body and the consequences of the removal of the thyroid and of the pancreas are familiar to us. In the case of the thyroid it has been demonstrated that when removed or when its function is arrested by disease the nitrogen elimination is much diminished and protoplasmic activity decreased, whilst the reverse condition obtains when the gland or extracts of it are administered. In contrast to this may be mentioned the effects of removal of three-quarters or more of the total renal tissue which is followed, as Dr. J. R. Bradford has shown, by an elimination on the part of the remaining portion of the organ of even more nitrogen than had taken place when both kidneys were untouched. This means an increased nitrogenous metabolism of the tissues apparently excited by the removal of the influence of the kidney, suggesting that this organ produces a something which inhibits, as the thyroid produces something which stimulates, the metabolism. Consistent with our general state of knowledge we are led to suppose this something is of ferment nature and that the internal secretions owe their activities to bodies of this class. Inasmuch as the normal influence of these organs is to promote oxidation and perhaps oxygenation in the sense just now defined it may be that a specific use of these organs is to furnish oxidising ferments to the economy. Important as is the integrity of these organs for the general well-being of the individual the range of their influence is far from being fully known and it is very uncertain how far the results of experiments in connexion with them conducted on the lower animals are applicable to man. There appears also to be some mutual relation in action among these organs, of which at present we have but only suggestions. Thus, for instance, the thymus ordinarily begins to atrophy when the sexual glands are becoming mature and castration in young animals (cattle, guinea-pigs, and rabbits) arrests the wasting of the thymus which continues to grow.[8] Dr. D. Noel Paton,[9] reversing the experiments and removing the thymus, was led to conclude that "there is a reciprocal action between thymus and testes, each checking the growth of the other." Similar relationships have been observed in respect to other organs. If, as is supposed, the effects on nutrition of these organs is an expression of ferment action it would seem that these ferments require for the manifestation of their activity the presence or absence of other like bodies, some being helpful as others are antagonistic.

THE RELATION OF LYMPHOCYTES TO NUTRITION.

In the consideration of the various factors engaged in maintaining the nutrition of the tissues mention must be made of one, the mode of action of which is not understood in anything like completeness, even if the suggestions which have been made so far are correct. It is well known that among the normal white corpuscles found in the blood are some characterised by a non-granular hyaline appearance, with a single large round nucleus, which are known as lymphocytes. Of these, there appear to be two varieties which differ chiefly in size. Ordinarily the proportion of these cells is about 25 per cent. of the leucocytes, but during the process of digestion it is found that this proportion is very much increased, subsequently to fall again to the before-mentioned number. So constant is this digestive lymphocytosis that it is impossible to avoid the conclusion that it is in some way connected with the digestive process itself or with the materials that result therefrom. It is in playing some part in the absorption of fats that the activity of the lymphocytes is assumed to lie, conveying it when digested from the columnar epithelial cells to the radicles of the lacteals. As in a measure confirming the nutritive importance of these cells is the undoubted fact of their greater number normally in the blood of children—at a time of life, that is, when the nutritive demands are greatest. And further, the greater activity of the adenoid tissue whence these cells are derived during infancy and childhood becomes even still greater in circumstances of impaired nutrition, as if by the increase in lymphocytes an effort was made to meet the deteriorating influences. It has been noticed that the diminution in the proportion of these cells to that which is characteristic of the adult occurs at about the time that the function of the thymus begins to subside. Neither the thymus nor the spleen, which together comprise the largest amount of lymphoid tissue in the bodies of young animals, however, appears to be essential to nutrition, for either or both have been removed without interfering "with nutrition, blood formation, growth, and development of the animal."[10] The subject is one of which we really know but little.

THE INFLUENCE OF THE NERVOUS SYSTEM ON NUTRITION.

There is yet another factor which requires to be taken into account when endeavouring to form anything like a complete conception of the processes of nutrition. In the progress of organic development, as the tissues and organs become differentiated and the functions specialised, there arises a demand, which grows with the increasing complexity of the organism, for some regulating, coördinating, and harmonising mechanism whereby the activities of the separate parts shall be combined most advantageously for the common good, to effect that union of action among the different organs as shall manifest most economically the life of the individual and most completely bring the organism into relation with its surroundings. This complex of functions is performed by the nervous system. I scarcely need stay to furnish you with examples showing the influence that the nervous system has over the nutrition of the separate tissues and organs or of the body as a whole. In health the existence of this function is assumed, but that some such influence really is present is apparent from certain morbid phenomena which are associated with its perversion, and in many cases also with an obvious structural lesion of the nervous apparatus. The well-known distribution of certain cutaneous eruptions in special nerve areas and the frequent morbid change found in the associated nervous tissue, such as herpes zoster, morphœa, "glossy skin," sclerodermia and others, atrophy of muscles and bones, bedsores and perforating ulcers, are but a few of the local results that we connect with a removal or perversion of this trophic influence due to disease of nerves or of nerve centres. There are other states of malnutrition in which there is a more general wasting but with which no special nervous change hitherto has been detected. Such an one is the condition known as *anorexia nervosa*, in which a universal and profound disturbance of the general nutrition is brought about, coupled with an almost complete abstinence from food. The degree of emaciation, however, far exceeds what occurs in professional fasters but is nevertheless compatible with an often remarkable degree of muscular vigour. It does not follow, however, that there are special neurons concerned with the discharge and conveyance of trophic impulses only but rather that these are involved in those nervous influences which govern the functions of the various organs and tissues and that "the function and nutrition of these [illegible] together an inseparable unity" [illegible] necessary to remark that by reg[illegible] nervous system also influences nutrition. It may be conceived that this trophic control may be exerted directly in stimulating the functional activity of the tissues, or, so to say, indirectly, as, for instance, by coördinating the mutual relationship of the tissues, one aspect of which we recognise as the effect of internal secretions, or by controlling that power of adjustment to the environment which is a fundamental property of living matter.

[10] Paton and Goodall: Proceedings of the Royal Society of Edinburgh, 1904.

If we attempt to form any conception of how the nervous system affects the processes of nutrition we should consistently with the nature of the function which I have set forth regard it as influencing the chemical processes within the cells. Direct structural continuity between the nerve fibrils and the protoplasm of many glands and muscles has long been known to exist, which shows at least the possibility of the nervous impulses immediately affecting the equilibrium of the cell. And, further, having regard to what we know of the nervous influence over the secretion of certain glands, we should not probably be far wrong in assuming that the anabolic and katabolic phases of nutrition are capable of being separately excited, though not necessarily by separate nerves. The increased and diminished action of the heart induced by stimulation of the sympathetic and vagus nerves respectively have been regarded by Gaskell as the result of the setting up of katabolic and anabolic processes in the cardiac muscle by these nerves, which, if a correct explanation—and there seems no reason to doubt it—illustrates the conveyance of synthetic and analytic stimuli by separate nerve paths. The mutual relation of the up-grade to the down-grade changes in the living cell and their continuous activity would presuppose an equally continuous emanation of nervous impulses from the cells of the centres governing nutrition, and that there is such a constantly passing influence has been maintained by Sir William R. Gowers[11] and others.[12]

THE RELATION OF IONS TO VITAL ACTIVITY AND NUTRITION.

So far I have traversed ground that is in the main well assured, indeed that in great part is familiar; and though there are many missing links in the chain of progressive changes which I have indicated to you there seems good reason to believe that those links will be discovered and that without any considerable upsetting of our present-day conceptions. The ascription to ferment action of the essential phenomena of nutrition does but give clear expression to many vague surmises that have long been held and the fact that the intimate nature of these substances is but most imperfectly known, or indeed their actual isolation but scarcely attained, does not warrant our refusing to regard them as the important factors that they are generally assumed to be. Nor should the simplicity of the idea lead us to reject it. To ascribe the wonderful series of changes that build up that marvellous material bioplasm with all its potentialities out of materials whose composition is for the most part well known, to these ferment bodies, to realise that these agents are capable of a reversible action largely due to the character of their environment, in short, to regard life as a series of fermentations brought about by the progressive and harmonious interaction of these enzymes, though it may not be the ultimate explanation of vitality, helps us one step further towards its realisation and does so in accordance with well-established data. But having gone so far, having acquired, so to say, another foothold from which to make further advance, speculation seeks for some means of explaining how it may be that the living matter liberates its activities which are thus regarded as dependent on ferment action.

Many years ago a Fellow of this College, Dr. S. Ringer, working with portions of contractile tissues, cilia and muscle, immersed in solutions of various substances, showed that the tissues continue to exhibit their contractility in certain solutions and not in others, the most suitable being a solution of salts similar to those found in the blood plasma. The real significance of these observations was not apparent and for a time they appear to have been lost sight of until the subject was a few years ago further investigated by Professor Loeb, formerly of Chicago and now of San Francisco. He found that the contraction is not manifested when the tissue is surrounded by solutions of such substances as urea, sugar, and albumin which are not electrolytes and that different contractile tissues differ in their degree of contractility according to the solution of electrolytes to which they are exposed. By varying the character of the medium he was able to start or arrest, quicken or slow, the action of a heart placed therein and could even make the limb muscle of a frog contract rhythmically like cardiac muscle. He went even further, and investigating that specific form of contractility which is represented by cell fission and that results in growth he found that he could initiate in the unfertilised ova of certain lower organisms by a suitable application of solutions of salts of certain strengths the cell division that characterises fertilisation and that is ordinarily regarded as the response peculiar to contact with the sperm cell. Similarly the irritability of nerve fibres has been shown by Dr. A. B. Mathews, a former colleague of Professor Loeb, to be controlled by the nature of the solutions with which it is bathed. The explanation for these remarkable phenomena, which refer more closely than before the manifestations of life "to their physical and chemical counterparts or analogies" (Burdon Sanderson), is to be found in the ionic theory of solution. In accordance with this hypothesis certain substances when dissolved undergo in the process of solution a more or less complete dissociation into their [illegible] of atoms, each of which becomes [illegible] with positive or negative elec[illegible] charged atoms are termed *ions*. It has been known since the time of Faraday that certain substances in solution through which an electric current is passed between two electrodes immersed in the solution also undergo a similar dissociation and some of the ions are set free at the positive electrode and are therefore regarded as carrying a negative electric change and hence called anions or negative ions; others are liberated at the negative electrode and are, therefore, called positive ions or cations. And those substances which behave thus under the passage of an electric current when in solution also undergo dissociation when entering into solution apart from the presence of a current. It is further found that the weaker the solution the greater is the percentage of dissociation into its constituent ions of the dissolved substance.[13] In solutions, particularly dilute solutions, these ions move freely about among the other parts of the liquid and diffuse through them, just as in a gas the individual molecules diffuse through the mass of the gas. And just as the moving molecules of a gas inclosed in a space tend to set up in that [illegible] tional to the number [illegible] a liquid tend to set up [illegible] pressure throughout the liquid and against the containing walls. If the containing walls be of porous membrane this pressure tends to drive the ions through the pores. This process of passage through the pores is known as osmosis and the osmotic pressure exercised by the ions of any given kind in a dilute solution is proportional to the quantity of the ions present in the solution.

Now, as a rule, the mass of living protoplasm is separated from the surrounding medium as the substance of the nucleus is separated from the cytoplasm by a membrane—cell wall. Whilst this structure may well serve to retain within the cell the cell contents, including zymogens, ferments, and other colloidal bodies, it will readily permit the passage outwards and also inwards of those diffusible substances in solution, which we have just seen in virtue of their solution have undergone ionic dissociation. It is also obvious that the degree of concentration of the fluid with which the cells are bathed and, adopting the terminology of Croft Hill, of the ana- and kata- products of metabolism will very considerably affect the nature and extent of the intracellular changes—that is to say, of the ferment action—that is to say, of the cell activity. The amount of water taken up or lost by a cell will thus influence very materially the direction of its action determining a synthetic or an analytic result.

---

[11] THE LANCET, May 10th, 1890, p. 1006.

[13] [illegible] and chemical [illegible] free in [illegible] Thus [illegible] ons and [illegible] would if separately added to water; no decomposition of the water by Na occurs nor is any free Cl detectable by its smell or its bleaching action.

I just now said that Professor Loeb has demonstrated that muscle varied in its contractility according to the electrolyte with which it is surrounded; thus sodium salts favour contraction as potassium and calcium salts inhibit it, but although this is the action of calcium it is nevertheless found that its *presence in very minute quantities along with the sodium* salt considerably prolongs the contractility of the muscle; with this circumstance it may be remembered, as suggesting the direction in which these salts act, that though the "influence of calcium is of doubtful value in the production of muscle-clotting or rigor mortis, its presence is most important in blood-clotting and milk-curdling" (Halliburton), all which changes are the result of ferment action upon which it may be supposed the influence of the calcium ions is brought to bear. In these cases the salt solutions are dilute; a concentrated solution of sodium chloride would kill a muscle immersed in it.

As giving some support to this theory of ionic action, Mr. S. W. Cole, as the result of experimental work on the *influence of electrolytes on the action of amylolytic* ferments,[14] found "that the action is favoured by anions and depressed by cations." This conclusion was justified by finding "that the salts of the strong acids accelerate the action of ptyalin on starch; the accelerating influence being the greater, the greater is the strength (avidity) of the acid. With salts of weak acids there may be a *retardation*; the more pronounced the weaker the acid is, and especially prominent in salts of dibasic and tribasic acids." Dr. Mathews, also, finding that some salts stimulate as others depress nerve action, attributes the stimulant effects to the action of anions and the depressing effects to positive ions.[15] In confirmation of this it is known that the electrical stimulation of a nerve always proceeds from the negative pole (cathode) on making the current.

Much work has been recently done on the intimate nature of colloids, of which the proteids that form the bulk of protoplasm consist. Constituted of small granules held in solution they are found to be capable of bearing an electrical charge, positive or negative, to be, that is to say, electrolytes, and among these bodies the ferments are to be included. "The salts or electrolytes in general," says Professor Loeb,[16] "do not exist in living tissues as such exclusively but are partly in combination with proteids. The salt or electrolyte molecules do not enter into this combination as a whole but through their ions. The great importance of these ion-proteid compounds lies in the fact that by the substitution of one ion for another the physical properties of the proteids change (for instance, their power to absorb water and their state of matter)." "It is more than probable that one or both of these qualities may account for muscular contractility and protoplasmic motion. The agencies which affect these two variable qualities of the protoplasm are, first of all, certain enzymes. Almost equally powerful are ions in certain concentrations."

Thus, then, the vital activities of the living cells would seem to consist essentially in the formation of ferment bodies which alone or in combination effect those integrations and disintegrations which liberate chemical energy and that this by transformation produces muscular work, nerve force, and secretory function, the fundamental manifestations of life. That these enzymes do bring about these changes in such conditions of temperature and alkalinity or acidity as obtain in the body appears to be certain; and as an explanation of the activity of the bioplasm which elaborates these bodies there is postulated an ionic action on the part of the cell contents and their surrounding medium whereby charges of electricity of variable strength and character are brought into conflict and that from the play of ions the manifestations of vitality result. Such a conception of bioplastic activity leads more clearly to the realisation of the inseparable unity of function and nutrition, and that nutrition in its fullest sense is life itself.

A CASE OF "SPLENOMEGALIC" OR "MYELOPATHIC" POLYCYTHÆMIA WITH TRUE PLETHORA AND ARTERIAL HYPERTONIA, WITHOUT CYANOSIS.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GERMAN HOSPITAL, LONDON.

IN the absence of cyanosis the following case differs from the cases of chronic cyanosis with polycythæmia and splenomegaly recorded by Vaquez, Saundby and Russell, Rosengart, Osler, and others. I have had the advantage of being able to study a typical example of such cases[2] and believe that the present case is really of the same nature but at an earlier stage and occurring in a fairly robust subject whose circulatory system is acting efficiently. I would temporarily include all these cases, with or without cyanosis, under one heading—namely, "splenomegalic polycythæmia," although I think it possible that the spleen need not be obviously enlarged to clinical examination in all cases. In many respects cases of this group, *like* the present one—*that* is to say, cases without cyanosis—resemble the case of "hypertonia polycythæmica" (Geisböck) recently recorded by Hess[3] but apparently differ from it in the absence of albuminuria and in the presence of splenomegaly.

The present patient, a Jewish woman, aged 37 years, of medium height and weight, first came under my care in July, 1903, for acute erythromelalgia of the left foot.[4] This condition under rest in bed and other treatment became less acute and finally gradually disappeared. The existence of the polycythæmia was first detected when the blood was examined in March, 1904, but was probably present earlier. From April, 1904, to February, 1905, the patient was constantly under observation in the German Hospital and on April 22nd, 1904, was shown at a clinical meeting of the Clinical Society of London. Owing to the disappearance of the erythromelalgia she is no longer confined to her bed. In fact, the condition for which she originally came under treatment is practically cured, though her other symptoms, objective and subjective, persist, and it is with these that the present paper deals.

There is no distinct cyanosis of the face, though the cutaneous blood-vessels are somewhat overfilled and the tongue is generally of a bright red colour with a bluish tinge resembling the colour of raw butcher's meat. The toes, especially those of the left foot, sometimes appear rather livid, but this is possibly connected with the past erythromelalgia, which, it should be remembered, was not entirely confined to the left foot. No evidence of disease has been discovered in the heart or the lungs. There is no dyspnœa. By examination of the abdomen nothing abnormal can be detected excepting moderate enlargement of the spleen, which can be felt one or two fingers' breadth below the ribs. For diagnostic purposes, owing to a question of the possibility of splenic tuberculosis, Koch's old tuberculin was employed in December, 1904, but the injection of five milligrammes failed to produce a reaction. Menstruation is regular. The bowels are sometimes confined. The urine is usually

Remarks—(*a*) The differential count was of 400 white cells by Dr. Eastes. During the count one mast cell was found. There were no myelocytes or erythroblasts. Three or four of the white cells counted were "intermediate forms" and Dr. Eastes enumerated these with the type which they most resembled (*b*) This blood count was made by Dr. Drys

estimation was by Dr Haldane. (*l*) The blood examination was of blood obtained by venesection containing 1 per cent. of a 50 per cent. aqueous solution of citrate of potassium. (*m*) The differential counts in 1905 were all of 500 white cells by Dr. Boycott as were all the others from Nov. 30th. Dr. Haldane estimated the hæmoglobin on Jan. 21st. In the blood films of Feb. 6th Dr. Boycott thought the changes in the red cells were much less marked than before and could only discover one normoblast with great difficulty.

the viscosity of the blood was excessive, higher than that of blood in all ordinary diseases and conditions.

Cryoscopy of the blood.—Some blood obtained at the venesection on Dec. 23rd, 1904 (mixed with 1 per cent. of a 50 per cent. aqueous solution of potassium citrate), was employed by Dr. W. d'Este Emery, clinical pathologist at King's College Hospital, to determine the freezing point, which he very kindly did on the day on which the blood was obtained. After the slight correction necessary for the presence of potassium citrate the freezing point was found to be minus 0·53° C., and therefore not very different from that of normal blood, which is about minus 0·56° C. The urine passed by the patient immediately after the venesection was of specific gravity 1008, faintly acid, and free from albumin and sugar. Dr. Emery found its freezing point was minus 0·79° C. Dr. Emery added that the blood plasma could not be collected in amount sufficient for the estimation of the freezing point, as after thorough centrifugalisation of a specimen of the citrated blood the plasma layer was only about two millimetres thick or, roughly speaking, only about 3 per cent. of the blood column.

The salts in the blood and urine.—On June 20th, 1904, Dr. Wright[17] estimated the salts in the blood as equivalent to 0·58 per cent. of sodium chloride (in lieu of the normal about 0·78 per cent.), the salts of the urine[18] coming out as equivalent to 0·46 per cent. of sodium chloride. This, Dr. Wright says, gives an excretory quotient of about 0·8 instead of the normal of over 2·0. However, on June 26th, 1904, he estimated the salts in the blood serum as equivalent to 1·14 per cent. of sodium chloride, whilst the salts in the fluid from a blister were equivalent to 0·95 per cent. of sodium chloride.

The alkalinity of the blood.—Dr. Wright estimated this on June 26th, 1904, as equivalent to that of a normal alkaline solution diluted 35 times. He expresses it as $\frac{N}{35}$.

The amount of albuminous substance in the blood plasma.—Dr. Wright found the amount in the citrated blood obtained on Dec. 23rd, 1904 (at the venesection), to be normal. His method of measuring the albuminous substances is by the resistance of the clot obtained by heating a graduated series of dilutions of the plasma.[19]

The coagulation of the blood.—Dr. Wright thought its occurrence was very much delayed on June 20th, 1904. Afterwards it appeared to occur fairly readily, but the exact coagulation time was not estimated.

The resistance of the red cells to hæmolytic agents.—Dr. Wright examined the citrated blood taken Dec. 23rd, 1904, by a method of his own and found the resistant power of the red cells to be about normal. One volume of centrifugalised sediment of red cells (the red cells were by repeated centrifugalisation washed fairly clean of blood-plasma) was suspended in sufficient $\frac{N}{10}$ salt solution to bring the total volume of the suspension up to three volumes. Complete hæmolysis was then obtained by adding one volume of the suspension in a capillary tube to one volume of a $\frac{N}{30}$ salt solution.

EFFECT OF TREATMENT AND PROGRESS OF THE CASE.

As already stated, it is exceedingly difficult to estimate how much the patient's condition has really altered apart from the improvement in the erythromelalgic extremity. She can now walk about quite well and has gained in weight, the erythromelalgia has disappeared, but the polycythæmia, high arterial tension, and the other phenomena in the blood and circulatory system persist, as do likewise the subjective symptoms (headache, &c.), although they vary in degree from time to time. Arsenic, which was employed by W. Türk[20] in his cases, was soon discontinued in the present case on account of a considerable apparent increase in the number of red corpuscles which followed its use. On the whole the patient has seemed to be better when on a diet containing relatively little meat and when taking lemon juice daily. It is possible that small doses of iodide of potassium or salicylates have a favourable influence. I have little doubt that absolute rest in bed, which was at one time required owing to the erythromelalgia, has an injurious influence on the general condition and some of the slight apparent improvement in the general condition may be due to the patient having been able to take a little exercise (favouring metabolic processes). Opium and its derivatives have not been given a trial. In regard to drugs, such as phenacetin and antifebrin (acetanilide), it must not be forgotten that the chronic use of antifebrin seems to give rise to cyanosis and blood changes.[21]

The venesection in the present case seemed to make no difference in the subjective or objective condition and it was not repeated, but perhaps the amount of blood (100 cubic centimetres) withdrawn was too little to produce any decided change. It may be noted also that the diminution in the number of red blood corpuscles observed on August 3rd, 1904, followed unusually copious menstruation.

The employment of Roentgen rays, which has lately been found to have such a decided effect in many cases of leukæmia, seems to have made no change in the number of red blood corpuscles in the present case. This is not to be wondered at since the action of these rays on the spleen and hæmopoietic tissues in leukæmia seems to be chiefly on the lymphocytes ("lymphocytolysis") and lymphadenoid tissues and on the leucocytes generally ("leucolysis").[22] It is, however, to be noted that after a good many Roentgen-ray sittings the patient complained more of headache or feeling of congestion in the head and this decided us to discontinue the treatment. The number of white cells in the cubic millimetre has been particularly low at recent counts (see Table I.) and the spleen has not been so easy to feel. It is possible, therefore, that the Roentgen rays, though they had no influence on the number of red blood cells, may have had a slight tardy effect on the spleen and on the formation of white cells analogous to that recorded in cases of leukæmia. The Roentgen-ray treatment was carried out by Dr. Mülberger, senior house surgeon at the German Hospital, who employed apparatus of Siemens and Halske of London, with direct street main supply; spark gap 25 centimetres; mercury dip break; 220 volts; 10 ampères; frequent breaks; hard tube (C. H. Müller, of Hamburg, No. 13, with vacuum-regulating apparatus); distance of the patient's skin from anticathode 50 centimetres; diaphragm compressor according to Dr. Faulhaber of Würzburg. The splenic region was subjected to the treatment for five minutes at every sitting and for one minute in addition every subsequent sitting till ten minutes were reached, after which the time of exposure was not changed. The treatment was carried out regularly, one sitting every day (Sundays excepted), from Sept. 15th to Oct. 8th, 1904, 21 sittings altogether. At nearly all of these sittings the lower parts of the legs were likewise exposed to the rays for five minutes.

In regard to future treatment it will be important to observe how the patient progresses now that she has left the hospital; in fact, the question is whether any special treatment is at present advisable or not. In the absence of all evidence that the disease is primary in the spleen I do not think that the operation of splenectomy can be recommended

REMARKS AND CONCLUSIONS.

As stated at the commencement of this paper I regard the present case, in spite of the absence of cyanosis, as similar in nature to my previous case[23] of splenomegalic polycythæmia. The excess of red corpuscles, true plethora ("polyhæmia") and arterial hypertonia were present in both cases. In the previous case the polycythæmia with the resulting increased viscosity of blood and increased strain on the circulatory mechanism was doubtless of older standing, the patient's vital powers were probably on the decline, and the cyanosis and relatively scanty urine may have been a result of a gradually developing inadequacy of the circulatory mechanism to compensate for the great viscosity of the blood (in spite of the presence of high arterial blood pressure).

The conclusions arrived at in my paper with Dr.

---

[23] Weber and Watson, loc. cit.

Watson as to a pathological activity in the production of erythrocytes in the bone marrow being the cause of the blood and circulatory phenomena have, I think, been amply confirmed by the present case. Our theoretical observations on a possible alteration in the osmotic tension of the blood may not have been required to explain the phenomena observed and, indeed, I shall not discuss that question here, as I have no fresh evidence to offer that there is any special change in regard to osmotic tension to be found in the symptom-complex under consideration.

In my previous case the existence of most extensive bone-marrow changes was proved by examination after death. A great portion of the normal bone marrow of the shafts of the long bones was found to have been replaced by red bone marrow, relatively free from fat, in which very active formation of red corpuscles was in progress as evidenced by the large quantity of erythroblasts. The changes were, however, not exclusively of an erythroblastic kind, and it may be doubted whether the erythrocyte-producing functions of the bone marrow can ever be greatly increased without the myelocytes being to some extent involved in the unusual activity. Dr. Boycott has pointed out that in the present case an abnormal activity of the bone marrow may not only account for the excess of red cells in the blood, for the great variations in their size (and for the variations noted in lesser degree in their shape and staining capacity), and for the presence of nucleated red cells, but likewise for the high percentage of polymorphonuclear leu[illegible] [illegible] ve been found in other cases of [illegible] There is no evidence pointing [illegible] lessened wearing out of red blood cells as a factor in the production of the anomalous blood condition. If the polycythæmia were due merely to concentration of the blood it would doubtless be only temporary and the blood would rapidly be diluted by fluid absorbed from the alimentary canal either directly into the blood capillaries or else into the lacteals to be thrown into the blood stream by way of the thoracic duct. Moreover, the fact that the total volume of blood in the body is abnormally great precludes the possibility that mere concentration of blood can be the cause of the blood changes. The clinical investigations of these blood changes, as already pointed out, as well as post-mortem examination, show that in cases of splenomegalic polycythæmia there is increased production of red corpuscles and I think the evidence is now really conclusive that the symptom-complex is always accompanied by, and at all events mainly due to, a pathological activity in the bone-marrow. Whether the latter condition can or cannot be regarded as the primary factor is a question to which I shall refer later. The objection to calling the symptom-complex "primary myelopathic polycythæmia" is that we are not sure that the disturbance of the bone marrow is necessarily the primary pathogenic factor; whilst the term "myelogenic polycythæmia" is insufficient, for every polycythæmia, excepting temporary states due to mere concentration of the blood, is "myelogenic" in the sense that the excess of red blood corpuscles is due to unusual activity of the bone marrow. On the other hand, the term "splenomegalic polycythæmia" only signifies that the spleen is usually enlarged, not that it must necessarily be found enlarged in every case.

I now believe the *order of development of the main symptoms* and their *causal connexion* to be as follows:—1. Increased erythroblastic activity involving a great part, but not necessarily the whole, of the bone marrow.[24] 2. Increased viscosity of the blood resulting from the polycythæmia. 3. Dilatation of small blood-vessels, partly to lessen resistance to the abnormally viscous blood, partly to make more room for dilution of the blood. 4. The "plethora vera" or "polyhæmia" is probably to be regarded as an attempt to compensate for the increased viscosity of the blood and for the excessive percentage of the total blood volume occupied by the cells. In fact, it is necessary, firstly, that there should be sufficient blood plasma to nourish the tissues and make metabolism possible; and, secondly, that the viscosity may not become so great as to render sufficient circulation impossible. 5. The arterial hypertonia is to be regarded as a result of the greater strain thrown on the circulatory mechanism. 6. Cyanosis, when this occurs, is probably due to inadequacy of the series of compensatory changes which, according to my view, precedes it.

In my opinion the evidence afforded by this and other cases strongly supports the foregoing conclusions, but the question now arises, *What is the nature of the pathological activity in the erythroblastic function of the bone marrow?* At least two theoretical explanations suggest themselves. In the first place that the bone-marrow activity is a primary one, allied to a tumour formation, or the result of an "idiosyncrasy" of the patient. One can suppose, for instance, that some persons have a bone marrow which reacts to ordinary erythroblastic stimuli to an excessive degree—viz., by throwing almost double the normal quantity of red cells into the blood stream. If, however, as H. Ribbert[25] believes there is a form of "myeloma"—that is to say, of growth originating in the elements of the bone marrow—which should be termed "erythroblastoma," because the tumour cells are related to erythroblasts, it seems possible that cases of splenomegalic polycythæmia, such as our two cases, may bear a relation to cases of erythroblastoma similar to that which lymphocytic leukæmia bears to lymphocytic myeloma.[26] The other explanation is that some toxin of a hæmolytic nature manufactured in the enlarged spleen or alimentary canal is absorbed into the circulating blood in minute quantities not sufficient to cause much hæmolysis but in amounts just sufficient to excite reaction in the hæmopoietic (erythroblastic) tissues. Metchnikoff quotes Belonovsky[27] of St. Petersburg as having increased both the number of corpuscles and the amount of hæmoglobin in the blood of anæmic persons by the injection of minute doses of hæmolytic serum.

I have just mentioned these [illegible] to the nature of the bone-marr[illegible] polycythæmia, but they are n[illegible] and I do not think it will be profitable to discuss them further without additional evidence.

The cause of the splenic enlargement.—If one inclines to the view that the bone-marrow condition in splenomegalic polycythæmia is the result of reaction to toxins circulating in the blood it is natural to suggest that the enlargement of the spleen is due to the same toxins, whether they enter the circulation from the intestines or elsewhere, or else that there is a primary disease of the spleen, such as tuberculosis (as there actually was in the case of Rendu and Widal[28] and some other cases), which gives rise to a condition of toxæmia to which the bone marrow reacts (excessive reaction being explained by idiosyncrasy) by an erythroblastic reaction resulting in polycythæmia. In favour of such a view there is the fact that in Saundby and Russell's case of splenomegalic polycythæmia with cyanosis Dr. J. W. Russell saw the patient with an enlarged spleen several years before cyanosis developed. To this I would answer that the polycythæmia was probably likewise present for years before the cyanosis developed and that cyanosis, if the views I have brought forward are correct, is not an essential part of the symptom-complex.

In my present case the enlargement of the spleen is not excessive and does not appear to be progressive and there is no fever or reaction to tuberculin to suggest the presence of tuberculosis. Splenic tuberculosis is certainly not necessarily present in cases of splenomegalic polycythæmia and primary tuberculosis of the spleen is not necessarily accompanied by polycythæmia.[30]

Possibly in the cases in which the splenic enlargement is due merely to increase of the pulp and engorgement with blood, as it seems to have been in my previous case, it may be explained as being due to the plethora vera (polyhæmia) and high blood pressure or as resulting from excessive functional activity in attempting to compensate for the excessive production of red corpuscles by increased destruction. Of these two last alternatives the former seems to me the most probable, as there is as yet no evidence of greatly increased destruction of red cells in these cases either occurring in the spleen or elsewhere.

Relation of erythromelalgia to polycythæmia.—There is no certain causal relationship and in the present case the association of the two conditions may have been a chance one, Yet it must be remembered that the association of splenomegalic polycythæmia with erythromelalgia has already been noted by W. Türk[31] of Vienna. I have elsewhere[32] given my reasons for believing that in the so-called "idiopathic or neuropathic erythromelalgia," as well as in what might be termed "symptomatic erythromelalgia" (that is, severe pain and redness in an extremity affected with decided arterial obstruction), there is obstruction to the supply of arterial blood, at all events during the chronic stages. In the present case the muscular atrophy and absorption of bone salts in the affected extremity[33] at one time pointed to local deficiency of arterial blood-supply. It is possible that when for any reason the supply of blood to the bone marrow of a long bone is greatly diminished the bone marrow may make an attempt to manufacture more blood; in fact, may undergo a hæmopoietic (erythroblastic and leucoblastic) reaction. Through the kindness of my colleague, Dr. E. Michels, in 1904 I had the opportunity of examining the tibia removed by amputation from an extremity affected by chronic arterial obstruction. There was some red metaplasia of the bone marrow at the ends of the shaft. In this case, however, the bone-marrow reaction may have been connected with the septic pyrexia preceding the amputation. Dr. J. Galloway also kindly showed me a patient with pain and redness in one foot undoubtedly due to arterial obstruction and informs me that in that patient the blood has been repeatedly examined and the number of red cells has always been found considerably above the normal. Such an increase in the number of red blood corpuscles was, however, not present in another somewhat analogous case, and further information is needed to find out whether chronic ischæmia of an extremity, which can notoriously give rise to local muscular and osseous atrophy, can likewise produce changes in the bone marrow of the affected part besides those due to absorption of fat cells.

I have to thank all those who have so kindly assisted me in the examination of this case, without whose assistance I could not have arrived at my few conclusions—in the first place, Dr. Haldane, Dr. Boycott, and Dr. Wright, and then Dr. J. H. Drysdale, Dr. Emery, Mr. Ryffel, and Dr. G. L. Eastes, and also (not least) the house physicians at the German Hospital, Dr. R. Blendinger and Dr. Schuh.

Addendum.—In cases of splenomegalic polycythæmia the onset of chronic cyanosis probably still further increases both the viscosity and the total volume of the blood. The effect of carbonic acid gas in increasing the viscosity of the blood has been clearly demonstrated by J. Bence[34] who states also that, according to Limbeck, an increase in the total volume of the blood accompanies the increase in the viscosity and adds that, according to Hamburger, this volumetric increase depends on an alteration in the osmotic relation between the red corpuscles and the blood plasma. Since writing the present paper I have come across an interesting account by W. Weintraud of three cases of splenomegalic polycythæmia.[35] The second of Weintraud's patients suffered also from a condition said to resemble erythromelalgia. In the same case, on one occasion, a remarkable improvement in the subjective symptoms followed a sharp attack of hæmatemesis.

SYMPTOMATOLOGIE ET DIAGNOSTIC DE L'ANGINE À SPIRILLES ET BACILLES FUSIFORMES (ANGINE DE VINCENT).

Par le Professeur H. Vincent.

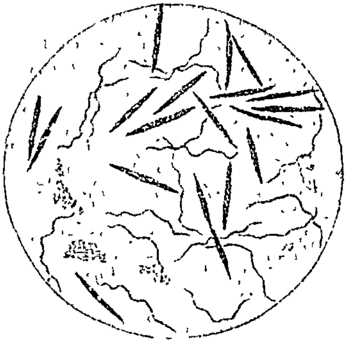
I.

La maladie que j'ai décrite sous le nom "d'angine à spirilles et bacilles fusiformes" présente une fréquence attestée par les nombreuses publications parues sur ce sujet. Elle peut s'observer à tous les âges, mais elle est surtout fréquente chez l'enfant vers l'âge de 8 à 10 ans et chez l'adulte de 18 à 30 ans. Au delà de 35 ans, elle devient certainement plus rare. D'après mes statistiques, cette angine s'observe dans la proportion de 2·26 pour 100 cas d'angines de toute autre nature (diphtérique, streptococcique, staphylococcique, colibacillaire, etc.), chez les adultes.

Cette maladie existe dans tous les pays, sous tous les climats et chez toutes les races, y compris la race nègre. Elle n'épargne même pas ceux qui prennent soin de l'hygiène de leur bouche. Cependant, elle est plus fréquente chez les sujets malpropres, chez ceux qui abusent du tabac ou de l'alcool, chez ceux qui ont des dents cariées. Cette angine a aussi des relations avec l'évolution dentaire. Tantôt seule, tantôt associée à la stomatite ulcéro-membraneuse (qui est due, le plus souvent, ainsi que je l'ai démontré, à l'infection par les mêmes microbes) l'angine se manifeste assez souvent au moment de la deuxième dentition et à l'époque de l'éruption des dents de sagesse. L'influence particulièrement favorisante du terrain sur l'éclosion de cette infection locale, est démontrée par sa fréquence chez les sujets anémiés par la misère physiologique, affaiblis par le surmenage; chez les syphilitiques et les tuberculeux; chez ceux qui vivent dans des logements malsains, mal aérés. Cette angine a une certaine prédilection pour les étudiants en médecine qui font la dissection, pour les garçons d'amphithéâtre d'anatomie,

etc. L'angine à bacilles fusiformes et spirilles est inoculable, soit chez le malade qui en est déjà porteur, soit chez un sujet sain, ainsi que je l'ai constaté. Queyrat a inoculé les microbes de cette maladie sur la muqueuse du sillon balano-préputial, chez un homme. On ne sera pas surpris de l'inoculabilité de cette maladie puisqu'elle est sous la dépendance des mêmes microbes pathogènes que ceux de la pourriture d'hôpital ou gangrène nosocomiale, que j'ai découverts en 1896. C'est pourquoi, aussi, cette angine est quelquefois contagieuse, à la suite de cohabitation, de contact intime ou de l'usage d'un même objet (verre à boire, cuillère, pipe, etc.).

Cette angine, appelée "maladie ou angine de Vincent," est déterminée par un *bacille* spécial ayant l'aspect d'un fuseau allongé. Les dimensions de ce bacille sont de 6 à 8μ pour les formes courtes ou moyennes, 10 à 12μ pour les formes longues. La largeur est de 1μ à 1μ 5. Examiné à l'état frais, dans la salive, ce bacille est tantôt assez mobile, tantôt peu mobile ou immobile. Il ne se colore pas par la méthode de Gram. La simple coloration de l'exsudat par la thionine, le violet phénique ou le liquide de Ziehl dilué, permet d'en obtenir des préparations satisfaisantes. Le microbe est reconnaissable à son aspect rectiligne, sa forme en fuseau, son protoplasma fréquemment vacuolaire. Il existe toujours en quantité abondante, parfois colossale, dans l'exsudat. A ce bacille s'associe en symbiose, dans la plupart des cas, un fin *spirillum* long, sinueux, très mobile, qui, dans les préparations colorées, offre un aspect tout différent de celui du bacille fusiforme et prend moins bien la matière colorante.



Angine à bacilles fusiformes et spirilles $\frac{1000}{1}$.

Les préparations des fausses membranes montrent ces deux microorganismes à l'état presque exclusif, malgré la présence d'innombrables bactéries étrangères diverses dans la cavité buccale. Les bacilles fusiformes et les spirilles semblent, en quelque sorte, "faire le vide" autour d'eux. Enfin il existe des cas dans lesquels le bacille fusiforme est seul, sans adjonction de spirilles. Quelquefois il est associé au streptocoque, au staphylocoque, au B. coli. Ces cas sont beaucoup plus rares.

Le bacille fusiforme est cultivable dans le bouillon ordinaire ou la gélose additionnée d'un tiers de liquide d'ascite, de sérum humain, de liquide d'hydrocèle, etc. Les cultures dégagent une odeur fétide. Le spirille n'est pas cultivable à l'air ou dans le vide.

II.

Il existe deux formes cliniques de l'angine, l'une diphtéroïde, très rare, que j'ai rencontrée dans 2 pour 100 des cas ; l'autre, ulcéro-membraneuse, la plus commune.

1 *La première forme* simule beaucoup la diphtérie. Elle débute par une légère douleur pharyngée et on constate un petit placard blanchâtre, d'abord mince, puis plus épais, qui s'élargit et repose sur la muqueuse rouge et enflammée. Cette membrane peu atteindre un ou deux centimètres de diamètre ; ses bords sont plus minces. Elle se laisse décoller et soulever. Elle est assez consistante. On voit alors qu'elle repose sur une surface exulcérée ou même saignante. Il existe de la dysphagie, une légère fétidité de l'haleine. Les ganglions sous-maxillaires sont habituellement tuméfiés. Une fièvre légère accompagne le début de cette forme d'angine. La durée de celle-ci est de quatre à huit jours, environ. Cette variété est déterminée par le bacille fusiforme seul ou associé soit au streptocoque, soit au staphylocoque, etc.

2. *La deuxième forme* de l'angine est, à la fois, la plus commune et la plus importante. C'est la forme *ulcéro-membraneuse.* Elle est déterminée par l'association du bacille fusiforme et du spirille. Elle est annoncée par du malaise, de la courbature, de la céphalalgie, de la fièvre, pendant deux ou trois jours, avec rougeur d'une amygdale ou d'un pilier et sensation de picotement. Parfois on voit un léger enduit blanchâtre. La fièvre atteint habituellement 37° C., 38° C., 39° C., et quelquefois davantage. Chez les enfants, il y a de l'agitation nocturne.

L'examen du pharynx montre bientôt une fausse membrane grisâtre ou jaunâtre, molle, peu épaisse, peu adhérente, sous laquelle la muqueuse est déjà exulcérée. L'amygdale est le siège le plus habituel de cette lésion. La fausse membrane augmente d'épaisseur (un millimètre et davantage) ; elle est molle, friable, facile à enlever et, vers le quatrième jour, elle repose sur une ulcération plus ou moins profonde, irrégulière, saignant facilement. L'amygdale est rouge, hypertrophiée, parfois de consistance assez dure. L'haleine du malade est particulièrement fétide. La langue est saburrale. La secrétion salivaire est exagérée. La déglutition est pénible, douloureuse. Les ganglions sous-maxillaires sont plus ou moins tuméfiés et sensibles dans les cas sérieux ou moyens ; ils sont peu gonflés ou même nuls dans les formes légères ou chroniques. Cette angine finit par guérir au bout de huit à quinze jours ; mais, chez certains malades, elle prend une marche chronique et peut persister, avec des alternatives d'amélioration et d'exacerbation pendant un mois, deux mois, et même six mois. Toutefois, ces cas, bien soignés, guérissent rapidement. J'ai observé dans 4 pour 100 des cas une amygdalite double. Il n'est pas rare d'observer la coexistence d'une stomatite ou gingivite de même nature fuso-spirillaire. Le processus ulcéreux déterminé par ces microbes est, quelquefois, très envahissant. Il peut gagner le voile du palais, la muqueuse de la langue, le pilier, après avoir intéressé la tonsille entière. Il peut même détruire entièrement la luette (Auché). Ces formes graves sont, cependant, exceptionnelles.

Les *érythèmes* scarlatiniforme, noueux, polymorphe, le purpura, ont été observés plus souvent. Il peut exister du *pseudo-rhumatisme* ordinairement bénin. L'embarras gastrique, l'inappétence, la constipation, sont fréquents. Je n'ai pas constaté de complications respiratoires. Cependant certaines complications graves peuvent apparaitre dans le cours de cette angine : albuminurie, myocardite, endocardite, etc. Mais ces complications résultent d'une infection surajoutée due, le plus souvent, au streptocoque.

III.

Le *diagnostic* de l'angine à bacilles fusiformes peut être assez difficile dans la forme diphtéroïde de la maladie ou bien à la première période de la forme ulcéro-membraneuse. La fausse membrane, l'adénite, la fièvre, peuvent faire penser à la diphtérie. Mais l'examen bactériologique montre immédiatement qu'il ne s'agit pas de diphtérie et que le bacille de Löffler est absent. Il importe de savoir, cependant, qu'il existe des diphtéries associées dans lesquelles le bacille de Loffler, au lieu d'être conjugué avec le streptocoque, le staphylocoque, etc. (comme c'est le cas le plus fréquent), est associé avec la symbiose fuso spirillaire. Dans ces cas la fausse membrane repose sur une ulcération plus ou moins évidente et la culture, ainsi que l'examen microscopique, viennent élucider le diagnostic.

A la *période d'état* de l'angine ulcéro membraneuse, les signes sont caractéristiques. Peut-être pourrait on penser à la diphtérie si l'ulcération est peu profonde Il est inutile de faire remarquer que la sérothérapie antidiphtérique est sans résultats et qu'il ne faut jamais négliger de pratiquer l'examen bactériologique de l'exsudat pseudo-membraneux. Les angines dues aux autres microbes : streptocoque, staphylocoque, pneumocoque, colibacille, leptothrix, oidium, etc., ainsi que les angines que j'ai appelées polymicrobiennes, n'offrent pas d'habitude les caractères cliniques de l'angine à bacilles fusiformes, avec son enduit jaunâtre ou crayeux, son ulcération *sous-jacente* l'odeur très fétide de la bouche, l'adénite. Les microbes spécifiques de l'angine de Vincent font, d'ailleurs, défaut Parfois on trouve ça et là quelques bacilles fusiformes dans les préparations microscopiques des angines polymicrobiennes, mais il n'y a pas, en réalité, de multiplication véritable de ces derniers microbes. Leur présence s'explique parce que le bacille fusiforme, de même que d'autres microbes pathogènes, est un hôte normal de la bouche des sujets sains. Cette dernière remarque s'applique aux lésions ulcéreuses diverses de la bouche et du pharynx, qui peuvent tantôt montrer quelques bacilles fusiformes, tantôt être littéralement envahies *secondairement* par l'infection fuso-spirillaire.

Une mention spéciale doit être faite pour le diagnostic différentiel de mon angine avec le chancre syphilitique ou les syphilides ulcéreuses de l'amygdale. L'angine à bacilles fusiformes a certainement été, parfois, confondue avec la syphilis des amygdales. Il est à remarquer, d'ailleurs, que la tonsille sous-jacente à l'infection fuso-spirillaire est souvent congestionnée et d'une consistance assez dure, et l'on peut alors penser, en présence de l'ulcération et de l'adénite, qu'il s'agit d'un chancre syphilitique. Cependant cette dureté modérée de l'amygdale n'est pas constante et n'est jamais aussi nette que dans le chancre spécifique. Enfin l'examen bactériologique vient lever tous les doutes. Mais il est important de savoir que les lésions syphilitiques secondaires ou tertiaires peuvent être infectées secondairement par le bacille fusiforme et les spirilles; ces microbes semblent avoir une certaine prédilection pour les ulcérations syphilitiques du pharynx. Dans ces cas, il est plus difficile de reconnaître la nature syphilitique de l'ulcération, dissimulée sous la fausse membrane. Il faudra, naturellement, tenir compte des accidents simultanés d'origine spécifique: roséole, plaques muqueuses, alopécie. Dans la syphilis, les ganglions cervicaux sont tuméfiés en même temps que les ganglions sous-maxillaires. Enfin le traitement servira de "*pierre de touche*" *ou de criterium essentiel. L'angine à* bacilles fusiformes est guérie en quelques jours si l'on frictionne deux fois par jour la lésion avec un tampon imprégné de teinture d'iode. Ce traitement est sans effet s'il y a une lésion syphilitique sous-jacente. Inversement le mercure et l'iodure de potassium déterminent la guérison de l'ulcération syphilitique, même si elle est compliquée par l'infection fuso-spirillaire; ce traitement n'amène, au contraire, aucune amélioration de l'angine que j'ai décrite.

TREATMENT OF COMPLETE UTERINE AND VAGINAL PROLAPSE.[1]

BY FREDERICK HOLME WIGGIN, M.D.,

FORMERLY VICE-PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION; AND PRESIDENT OF THE NEW YORK STATE MEDICAL ASSOCIATION; VISITING FELLOW OF THE NEW YORK ACADEMY OF MEDICINE; VISITING SURGEON TO THE NEW YORK CITY HOSPITAL; AND GYNÆCOLOGIST TO ST. ELIZABETH'S HOSPITAL, ETC.

So much diversity of opinion still exists among gynecic surgeons as to the proper treatment to be employed for the cure of complete uterine and vaginal prolapse that it seems timely again to bring this subject forward for discussion; and for this reason I desire to place before you for consideration the method of treatment which in my experience has proved the most satisfactory. Before

---

[1] A paper read at the annual meeting of the American Medical Association, held at Atlantic City, N.J., on June 9th, 1904, before the Section on Obstetrics and Diseases of Women.

doing this, however, a few words in regard to the pathology of the disorder may be of interest. The condition is best described as a reducible hernia through the pelvic floor, the sac being the inverted vagina, containing, besides the uterus, the tubes, the ovaries, the bladder, and the rectum, a large portion of the small intestines. The causation of the disorder, as is well known, is primarily a separation—often submucous—of the tendons of the muscles forming the pelvic floor where they unite in the median line and is usually due to the passage of the child's head during parturition. This separation of the tissues, which hold the rectum in its proper position, allows the lower anterior portion of the gut to bulge upward and forward into the vagina, pushing the vaginal tissues before it. This abnormal position of the bowel is increased by every act of defæcation and straining at stool and is also added to by the lifting of heavy weights. As the muscular force employed follows the line of least resistance it tends in these cases not to expel the bowel contents through the anus, as it should, but instead to force the gut forward through the hernial opening into the vagina. The difficulty experienced by the sufferer in emptying her rectum causes her to exert an ever-increasing force and gradually and steadily, day by day, the rectocele increases in size, force in a downward direction being necessarily applied to the attached uterus and its ligaments, which in a normal condition serve simply as stays holding it in place, are gradually stretched and lengthened, allowing greater freedom of position to the descending organ. As the uterus descends the bladder goes with it. The descending process is hastened, after it has fairly begun, by the added weight of the small intestines, which being contained largely in the pelvis find their way by gravity to the lowest point. Thus after a period of a longer or shorter duration, varying usually in accordance with the natural vigour of the patient and the amount and character of the work she is called upon by reason of her environment to perform, a complete inversion of the vagina occurs and a hernial sac of large size appears outside the body and we have the condition known as complete uterine and vaginal prolapse to deal with. This complete form of the disease does not, as a rule, appear until rather late in life, although the patient has probably suffered from much discomfort and disability for many years.

In the surgical treatment of this disorder much ingenuity has been displayed. Various operations on the anterior and posterior vaginal walls, as well as the removal of the uterus in whole or in part, have been recommended, but unfortunately without very satisfactory results. In my opinion, these disappointing results have been due to the operator's failure in most instances to recognise the fact that the vaginal wall in these cases is a hernial sac with other contents than the uterus, tubes, ovaries, bladder and rectum, and that consequently the simple repair of the external perineal body, the removal of a larger or smaller portion of the vaginal walls, or even the removal of the uterus itself, would not correct the greatest cause of the difficulty—namely, the abnormal position of the small intestines. In the elderly patients suffering from this disease who have come under my observation, many of them having external tumours of large size, the uterus has not been found abnormally enlarged and consequently could not be considered a factor in the causation of the trouble and many patients have come under observation upon whom a hysterectomy for the cure of this disorder had been previously performed by other surgeons who stated that their tumours were larger than before operation.

In view of the foregoing facts it seems clear that the operative procedures required for the successful treatment of the class of cases under consideration are those that will first obliterate the inverted and stretched vaginal wall—which is in reality a hernial sac—and then restore the damaged perineal structures and distended anterior vaginal wall as nearly as possible to their normal condition. The technique which has, in my experience, best answered these requirements has been the following. The patient on coming under observation is placed in bed in the recumbent posture and the tumour is reduced, gravity being employed to help retain the parts in their normal position by raising the foot of the bed about six inches. Tampons moistened with glycozone are placed in position and the parts treated until all the ulcerated portions of the vaginal walls have healed, the general condition of the patient being meanwhile carefully looked after. The next step in the procedure is the performance of a laparotomy after the usual preparations have been made, the patient being placed in the Trendelenburg posture before the abdomen is opened for the purpose of obtaining the aid of gravity in drawing the parts back into their normal position. The bowels are usually in these cases found to be more or less attached to the vaginal wall by adhesions which must be broken up. The uterus, which, as has been previously stated, is in elderly women usually small, is found and pulled upward by the aid of bullet forceps, drawing the vaginal wall upward also. When this has been accomplished a needle armed with large size kangaroo tendon is passed through the fibres of the uterus at the point of its attachment to the round ligament and carried down the broad ligament in the form of a purse-string suture (see Fig. 1) and back again, the needle being finally made to emerge at about the point of entrance, so that when the two ends of the suture are drawn upon the broad ligament on that side is folded up and drawn together, thus doing away with its excessive length and giving the uterus a new point of attachment near the insertion of this ligament at the pelvic brim (see Fig. 2).

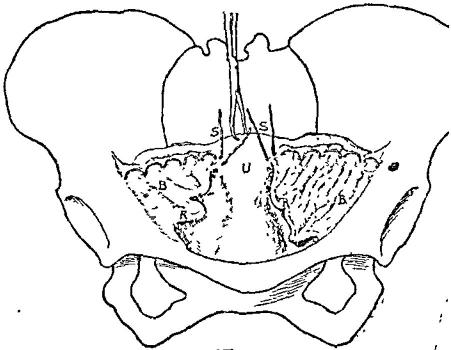

Fig I

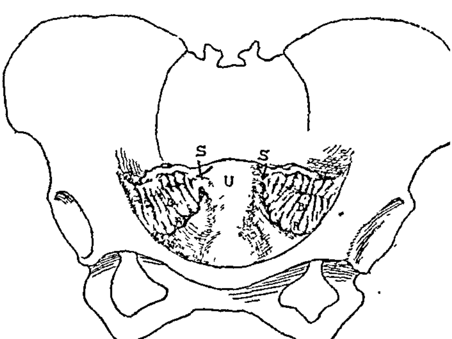

Fig II

B B, Broad ligament. R R, Round ligament. S S, Sutures. U, Uterus.

The same process is repeated on the opposite side. The abdominal cavity is then flushed with saline solution, some of which is allowed to remain, and the wound in the abdominal wall is rapidly closed by means of buried sutures and protected by a celloidin dressing. If the patient is then in ordinarily good condition repair of the pelvic floor and reduction in size of the anterior vaginal wall are undertaken. In my experience there is usually no difficulty in accomplishing this, for all the operative measures necessary to make a complete cure can easily be performed in 40 minutes. In these operations time is an important factor, as most of the patients are elderly and do not bear prolonged [illegible] procedures well, or those involving much loss o[illegible] *hence the importance of not removing the uterus in w[illegible] part when it is not at fault in the treatment of this disorder.* Many operations such as have just been described have been performed by me during the last few years on women whose ages ranged from 60 to 83 years, without mortality and with most satisfactory results.

New York City.

CARCINOMA OF THE UTERUS AND ITS SURGICAL TREATMENT.

BY EDWARD T. THRING, F.R.C.S. ENG., L.R.C.P. LOND.,

SURGEON TO THE PRINCE ALFRED HOSPITAL, SYDNEY, ETC.

THE following brief notes of six cases of carcinoma of the uterus are given simply as examples of the method which, I believe, gives the best final result in those instances in which removal of the uterus is justified.

CASE 1.—The patient, a nullipara, married, aged 32 years, was first seen on Dec. 15th, 1894. She gave a history of repeated attacks of pelvic peritonitis, probably the result of an infective salpingitis. The menses had been regular every four weeks; of late there had been occasional blood-stained discharge between the periods. On examination the uterus was fixed and retroverted; both ovaries were cystic and of about the size of a large orange. From the posterior lip of the cervix was a fungating mass which bled readily on being touched. A portion removed for microscopic examination showed it to be carcinoma. Operation was performed on Dec. 24th. The uterus, ovaries, Fallopian tubes, and broad ligament were removed; also the pelvic glands. On section under the microscope two glands from the left side showed carcinomatous change. Five months after the operation a small recurrent nodule was excised from the scar in the vault of the vagina. There was no further recurrence. The patient is now (Feb. 4th, 1905) quite well.

CASE 2.—The patient, a nullipara, married, aged 50 years, was first seen on Feb. 16th, 1897. She complained of pain in the left side of the pelvis. The menopause took place three years and three months previously; "nothing seen" for two years and three months, then a "flooding" occurred and since then there had been slight irregular bleedings. Of late a bad-smelling discharge had been present. On examination the uterus was still of normal size—i.e., not atrophied; it occupied a good position, was tender to touch, and slight bleeding occurred after examination. Operation was performed on March 19th. The uterus and appendages, together with the broad ligament and the pelvic glands, were removed. Two glands from the left side of the pelvis showed carcinomatous infiltration. This patient lived for six years well; she then became ill and died during the seventh year from "Bright's disease." She was not under my care at that time.

CASE 3.—The patient, married, aged 51 years, was first seen on August 12th, 1900. The menopause occurred seven years previously. Three months previously a "sudden gush" of blood took place; slight bleeding had been present ever since but no pain. On examination there was nothing abnormal in the thorax or abdomen. The uterus was of full size and not atrophied; there was an old cervical tear. The sound entered two and three-quarter inches, followed by blood from the os. Operation was performed on August 25th. The uterus and appendages, together with the broad ligament and the pelvic glands on both sides, were removed. The uterus showed carcinoma of the body growing from near the right cornu; also two glands from the right side of the pelvis were infiltrated by carcinomatous deposit. This patient is now (February, 1905) alive and well.

CASE 4.—The patient, a multipara, married, aged 46 years, was first seen on March 14th, 1900. The menses had been regular every four weeks. She had had a "watery discharge" for nearly six months; this was sometimes blood-stained. On examination a fungating ulcerated growth from the cervix was seen; this bled readily on being touched. The uterus was apparently free from adhesions. Operation was performed on March 21st. The uterus and appendages, together with the broad ligament and the pelvic glands on both sides, were removed. In this case there was carcinomatous infiltration of the glands from both the right and [illegible]st marked, however, on the right. During the [illegible] was found to be easier to ligature the internal [illegible] the uterine artery far back; this [illegible] in dissecting out the pelvic glands. On the *fourth day* there was a leakage of urine into the vagina, although a considerable amount was also drawn off through the urethra. This leakage gradually diminished and ceased entirely on the twelfth day. I received a letter from this patient on Jan. 26th, 1905 in which she says that she is, and has been, perfectly well since her convalescence after the operation.

CASE 5.—The patient, a multipara, married, aged 33 years, was first seen on July 1st, 1901. There was a history of severe bleeding from the vagina. The patient was blanched. On examination there was found a fungating growth from the cervix. This was removed with a sharp spoon to control the bleeding temporarily. Operation was performed on July 19th. The uterus and appendages, with the broad ligament and pelvic glands, were removed. The glands on the right side were infiltrated with carcinomatous deposit. The fungating mass was a cylindrical-celled carcinoma. The patient is now (February, 1905) well.

CASE 6.—The patient, a multipara, married, aged 34 years, was first seen on Jan. 2nd, 1903. The menses had been regular every four weeks up to August, 1902, then "floodings" occurred at each period, also some bleeding between times. The patient was blanched and breathless. On examination a fungating bleeding growth from the cervix uteri could be seen. On bimanual examination a gland on the left side of the pelvis, of the size of a pigeon's egg, slightly moveable, could be felt. Operation was performed on Jan. 14th The uterus and appendages, broad ligament, and pelvic glands were removed. The glands on both sides were infiltrated by carcinomatous deposit; this was more advanced in those of the left side. The patient when last seen a short time ago was well and there were no physical signs of recurrence.

I [illegible] brief notes of these six instances of [illegible]as simply as illustrative cases. All occurred in my private practice and I was therefore able to follow them more closely than is usually possible in hospital practice. They are only a small number of those operated upon during the past ten years but they demonstrate the points which I wish to emphasise.

In each case the growth was examined microscopically. In each the pelvic glands were the seat of carcinomatous deposit secondary to the uterine growth. In one only could it be demonstrated before operation that there was involvement of pelvic glands—i.e., Case 6—the most recent one. The leakage of urine in Case 4 was, I believe, the result of trophic changes either in the base of the bladder or in the right ureter near the bladder and due to the fact that the right internal iliac artery itself was ligatured and not the anterior division of it or the uterine trunk. That there was no lesion at the operation is proved by the fact that there was no leakage until the fourth day after. I have seen this happen three times, and in each case the leakage only lasted a few days and ceased spontaneously; and in each of the three cases either the right or left internal iliac artery had been tied and divided. In two cases this was done to facilitate access to the deeper glands lying against the internal iliac vein. I have not met with any instance of septic cystitis spreading up along the ureters to the pelvis of the kidney, such as are recorded in the *Johns Hopkins Hospital Bulletin* for May, 1904. I think that this may be due to the fact that, recognising there must of necessity be a great deal of serous oozing after such an operation and also that, owing to the free removal of peritoneum, it is often difficult to obtain sufficient to cover over the exposed ureters and base of the bladder; I have made it a practice to pack the lower part of the pelvis lightly with a long strip of several thicknesses of iodoform gauze, bringing one end out into the vagina and so providing very free escape for the serum instead of the small drain which is apparently used at the Johns Hopkins Hospital in such cases.

The chief point, however, to which I desire to call attention is the fact that in all these cases the pelvic glands were more or less the seat of secondary carcinomatous deposit and that by no possibility could these glands have been removed had the ordinary vaginal operation of hysterectomy been performed. They can *only* be dissected out through an abdominal incision Further, I think it must be granted that in each of the six cases the patient s hope of "cure" would have been *nil* had the glands been allowed to remain and that although in only two cases has the five years' *limit been well passed and in two others* almost, but not quite, reached still, not one of these four would now be alive or have survived at the outside more than three years In the two more recently done cases it must be allowed that they, at all events, have a fair chance of "cure" which otherwise would have been an impossibility On reading the report of the Gynæcological Section at the last meeting of the British Medical Association in England I saw that Professor Olshausen definitely condemned any other major operative procedure in carcinoma of the uterus than vaginal hysterectomy, stating also that it was impossible to know beforehand whether the pelvic glands were involved or not except, of cour e, in advanced and inoperable cases This was used as an argument in favour of vaginal hysterectomy and against any more radical operation Surely it ought to be the other way about The few cases I have cited and many more could be adduced, seem to prove this Another argument used against the more thorough and radical operation was its great mortality, as stated by [illegible] I have found it to be [illegible] ht —above the 3½ per [illegible] to the vaginal opera [illegible] er such an added risk [illegible] is greater, and that this must be so I think [illegible]

I am aware that in [illegible] sition to all the speaker [illegible] referred to, but the facts seem to justify the position I have taken for the past ten years—i e , in all cases of carcinoma of the uterus, where a maj [illegible] one admissible is that one [illegible] "cure," provided that the [illegible] To leave the pelvic glands behind in such cases is to jeopardise the patient s chances of "cure small as they may be at best I have not given a detailed account of the steps of the operation as I usually do it because I have already done so in the *Journal of Obstetrics and Gynæcology of the British Empire* for January 1903

Sydney New South Wales

THE TECHNIQUE OF THE OPERATION FOR ADENOIDS AND ENLARGED TONSILS, WITH SOME PRACTICAL SUGGESTIONS

BY FREDERICK O CARLE M.B LOND , M R C S ENG

SENIOR CLINICAL ASSISTANT TO THE THROAT HOSPITAL GOLDEN SQUARE W

THE operation for adenoid growths and enlarged tonsils now so extensively practised is in reality a more complicated surgical procedure than it appears to the casual observer To perform the operation efficiently so as to obtain the greatest amount of benefit to the patient and satisfaction to the surgeon considerable skill is required which is only obtained by extensive practice Many untoward after effects come before the surgeon s notice which he learns by experience how best to avoid When one remembers that the completeness of the surgical measures employed is estimated by touch at the time of operation without directly viewing the area operated upon it will be readily appreciated that it is only by constant practice the surgeon is able to detect any incompleteness of his work by touch alone

A description [illegible] practised at the Throat [illegible] less clear up many difficu [illegible] ith A C E mixture on a flat table Any pillow placed beneath the patient s head should be removed before the operation is commenced The head thus maintains its normal relation to the trunk upon which it is neither flexed nor extended The importance of this I shall point out later The degree of anæsthesia should be such that the conjunctival reflex is lost but not the reflex to light A gag preferably Doyen s is now introduced by the anæsthetist and the mouth well opened The head is steadied by the anæsthetist The surgeon, standing on the right side of his patient introduces the forefinger of his left hand to depress the tongue thus bringing into view the soft palate and uvula A StClair Thomson s adenoid curette is carefully passed behind the soft palate into the naso pharynx The handle of the curette is well depressed, so as to cause the cutting *edge of the instrument to impinge against the base of the* septum The handle of the curette is carried through a semicircle considerable pressure being used in making the cutting edge travel across the pharyngeal vault In the latter part of the stroke so much pressure is not desirable for fear of cutting too deeply into the muscular tissue of the posterior pharyngeal wall On withdrawing the instrument the mass of adenoid tissue is found in the cage of the instrument The patient is immediately turned on to his right side the nurse taking charge of the body and the anæsthetist of the head The tonsils are next removed with a Heath s guillotine, the lower or right first The surgeon defines the tonsil with his left forefinger introduces the guillotine and slips the ring over the organ The handle of the instrument is carried well over to the oppo ite side when the blade is pressed home and the tonsil removed The upper or left is removed in a corresponding manner, the surgeon reversing his grasp of the handle in his right hand The fauces and post nasal space are then carefully palpated with the forefinger and any remaining adenoid tissue detected is removed with a Gottstein's curette The violence of the bleeding is allowed to abate when the patient is removed to bed in a prone position with the head low, a towel being held to the face during transit to catch any blood

The practical points to which I would call attention are as follows The horizontal position of the patient in the dorsal decubitus, the head being neither flexed nor extended With the head extended the cervical curve of the spinal column is increased in this position the operator is liable to cut deeply into the muscular structures of the posterior pharyngeal wall which will be stripped down by the curette leaving extensive tags of muscle and mucous membrane These will slough and give rise to unpleasant symptoms in the after treatment so making the patient more liable to acute middle ear inflammation a not infrequent result of the operation for adenoids The lateral position favours the drainage of blood from the pharynx out through the mouth and in no way inconveniences the surgeon in removing the tonsils In removing the tonsils a small guillotine is better than a large one since the encircled organ is not so liable to slip out of the smaller ring The lower end of the tonsil hangs down into the pharynx and does not merely project from between the faucial pillars In removal therefore it is important to get the lower edge of the guillotine ring below this projection and to thread the ring on to the tonsil from below upwards The posterior pharyngeal wall is best cleared at the end of the operation by scraping with the finger nail from below upwards, thus avoiding tearing downwards of the posterior pharyngeal wall as is liable to follow the use of a curette Large buried tonsils are best dealt with by removing a thin slice followed by breaking down of the tonsil tissue with the finger The cicatricial contraction following this method of procedure markedly reduces the size of the hypertrophied organ The results obtained by the above method of operating are eminently satisfactory any after ill effect rarely occurring

ANATOMICAL PECULIARITIES OF A GALL BLADDER AND AN APPENDIX

BY FERGUSON LEMON, M B , B S MELB

AN instance of inclusion of a gall bladder in the substance of the liver presented itself recently while Dr W K Bouton of Melbourne was operating for gall stones After opening the abdomen in the manner recommended by Mr A W Mayo Robson for this [illegible] of operation the liver presented itself in the operation wound and what appeared to be a hydatid cyst was seen on the anterior surface of the right lobe—a slightly rounded elevation of pale yellowish colour On lifting the liver forward a similar though somewhat more projecting eminence appeared on the posterior surface which when viewed through the substance of the liver was quite translucent It was in the normal position for a gall-bladder but the surfaces, both anterior and posterior, were continuous with the liver substance. As no gall-bladder could be discovered an incision was made on the posterior surface into the swelling when bile gushed out, and on further exploration two large gall-stones, one barrel-shaped and the other conical, were secured; there was an additional facet on the barrel-shaped stone showing that a third stone had been present, but as a probe passed the whole length of the common duct without striking one it had evidently been passed previously. The edge of the incision into the gall-bladder at the time of operation was at least three-eighths of an inch thick, the circularly arranged coat of the gall-bladder being marked off very definitely from the liver substance on the one hand and the mucosa, &c., of the bladder on the other. Having secured a specimen for microscopical examination the usual procedure for closing the abdomen and draining the gall bladder was undertaken. On examination with the naked eye after the usual hardening process the specimen measured about three millimetres and showed the same three layers as already mentioned. Under low power the layers were made up of (1) an outer thick layer of connective tissue, probably a continuation of Glisson's capsule; (2) a circularly arranged layer of connective tissue, evidently the true covering of the gall-bladder; and (3) the mucosa, muscular tissue, &c., of the gall-bladder. The thickness of the anterior surface of the bladder and liver appeared to be slightly more than that of the posterior surface, but no section was made of it.

Curiously enough on the same day at another operation for appendicitis a divergence from the normal was seen in the appendix. On lifting the cæcum into view a small elevation on the anterior surface of the cæcum, about five inches from the extremity of the gut, was seen from which a little pus oozed. At first sight it looked like a perforation of the cæcum itself, as no trace of the appendix connected with it could be seen, but on further examination a little loop of appendix with a diameter of half an inch sprang from the extremity of the gut and, passing upwards, appeared to end in the cæcum half an inch away from its origin. No elevation appeared on the smooth peritoneal surface to indicate that the loop had any connexion with the perforated elevation four and a half inches distant. However, taking the loop as a guide and carefully dissecting away the peritoneum the appendix was traced till it ended in the elevation. The appendix was then stripped off the cæcum and removed in the ordinary manner. The exposed surface beneath was the muscular tissue of the cæcum and it bled freely. After careful application of a continuous suture of fine catgut through the free edges of the peritoneum, including some of the muscular layer, the bleeding was stopped, and for further security a second row was inserted invaginating the first and including the stump of the appendix. The abdomen was then closed.

Both cases did excellently. I am indebted to Dr. Bouton for permission to publish them.

Hawthorn, Victoria, Australia.

CÆSAREAN SECTION FOR CONGENITAL MALFORMATION OF THE CERVIX UTERI; RECOVERY.

BY H. TRAILL SKAE, M.B., CH.B. ABERD.,
HONORARY DISTRICT SURGEON TO THE ROYAL MATERNITY CHARITY.

THE patient, aged 24 years, married, pregnant for the first time, was taken in labour early on June 12th, 1904, being then seven and a half months pregnant. She was a well-built, healthy woman. Her menstrual history was normal except that she sometimes had a good deal of pain. She was seen about 1 P.M. by a medical man of much experience who found an apparent absence of the cervix but did not interfere. At 9 P.M. he handed the patient into the care of my partner, Dr. W. D. G. Mulloy, who subsequently asked me to examine her with a view to operation. The patient had then been in strong labour for about 12 hours and was becoming exhausted. The liquor amnii was stated to have been dribbling away all day. The patient was emphatic in saying that she had felt the child move a few hours before.

On examination at 10.30 P.M. pains were found to be frequent and sharp but of short duration. The patient was a well-formed woman with no abnormality of the bony pelvis. The fundus uteri was one and a half inches above the umbilicus (most of the liquor amnii had dribbled away). The fœtal head could be felt above the pubes. The external genitals were normal. The vagina was unusually short, the finger being brought to a standstill quite unexpectedly, and just for a moment the impression of total absence of a cervix was strikingly given. The vaginal walls were quite lax and undilated. On further examination it was found that the vaginal cervix was represented by a small flat warty projection, somewhat irregular and quite hard and firm. At its centre was the os—a small opening hardly large enough to admit a probe. This projection was placed almost in contact with the rectal wall, the posterior fornix being almost unrepresented. A slimy purulent discharge was oozing from the opening. The fœtal head could not be distinctly felt through the vagina. No fœtal movements could be felt and the heart sounds were not to be heard. It was evident that there would be much difficulty in introducing any instrument to dilate the os and further, that any attempt to dilate would inevitably result in rupture into the rectum. And as it appeared advisable to sterilise the patient by tying and dividing the Fallopian tubes abdominal Cæsarean section was decided upon. (Permission to sterilise was, however, subsequently refused.) Sedatives were given to enable the patient to get some rest.

At 11 A.M. on the next day chloroform was administered by Dr. R. Purdie, the patient having been prepared in the usual way, and Dr. Mulloy assisted me in the operation. The abdomen and uterus were opened in the middle line, an elastic ligature being placed round the latter. This tourniquet had afterwards to be temporarily loosened as it was found to have caught the fœtal scalp; bleeding, however, was readily controlled with the hands. The fœtus had evidently been dead for some days as putrefactive decomposition was well marked. The placenta, attached to the posterior wall of the uterus, was soft and foul-smelling—quite putrid. The uterus was emptied and scraped and then swabbed with perchloride solution (1 in 2000) followed by sterilised water. With considerable difficulty a narrow strip of gauze was forced into the vagina, about one and a half inches projecting into the uterus to act as a drain. The uterus was closed with deep and superficial sutures and contracted well. The abdominal wall was sutured in one layer and dressed. Vaginal douches of izal were given twice daily. There was a little feverishness for some days owing to the imperfect drainage from the uterus. The gauze drain was expelled on the fifth day. The perchloride swabbing caused no ill-effects and the patient made a good recovery.

There was no history of any malformation in the patient's family.

Hampstead, N.W.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

A Case of "Splenomegalic" or "Myelopathic" Polycythæmia with True Plethora and Arterial Hypertonia, without Cyanosis.

A MEETING of this society was held on May 9th, Mr. H. T. BUTLIN, Vice-President, being in the chair.

Dr. F. PARKES WEBER read a paper on a case of "Splenomegalic" or "Myelopathic" Polycythæmia with True Plethora and Arterial Hypertonia, without Cyanosis, which is published in full in this issue of THE LANCET.

Dr. J. S. HALDANE agreed that all facts pointed to an increase in the activity of the bone marrow as the cause of the polycythæmia. The method of determining the total volume of blood by the carbon-monoxide method gave results which were identical with results obtained by older methods. He referred to the extraordinary constancy of the ratio of the hæmoglobin and of the total blood volume to the body weight under various conditions. In the case under consideration, however, the blood volume was nearly double the normal ratio. The patient's condition was similar to that of an animal into which blood from another animal had been injected—there were an increase in the percentage of hæmoglobin and an enormous increase in the number of blood cells.

He suggested that extensive bleeding might be resorted to in treatment of this condition

Dr A J **WHITING** referred to the enlargement of the spleen in this condition and said that experimentally by copious bleeding of animals the bone marrow underwent hypertrophy and at the same time the spleen became swollen and of a rosy red colour and microscopically was hardly distinguishable from bone marrow He asked whether the spleen had been examined in Dr Parkes Weber's first case and what changes had been found

Dr A E **BOYCOTT** said that he had dealt only with the pathology of the blood Apart from the increase in the hæmoglobin and in the number of cells he had found a distinct alteration in the size of the blood cells some being larger, and others smaller, than normal The staining reaction of the cells was altered and a small number of nucleated red cells were constantly present The polymorpho neutrophile cells were always present in a high percentage

Dr **PARKES WEBER** in reply, said that very little change could be seen in the sections of the spleen which had been examined Only an increase of the spleen pulp was present

MEDICAL SOCIETY OF LONDON

General Meeting —Discussion on the Perineal and Suprapubic Methods of Prostatectomy

THE annual general meeting of this society was held on May 8th Mr **JOHN LANGTON** the President, being in the chair

The annual reports of the council the honorary librarian and the chairmen of the house and finance committees were received and adopted and the election of the officers and council for the ensuing year took place The result of the ballot was as follows President Sir Lauder Brunton Vice Presidents, Dr Edward J Nix Mr Charters J Symonds Dr William Pasteur, and Mr C W Mansell Moullin, treasurer Mr David H Goodsall, librarian, Dr Arthur Francis Voelcker, honorary secretaries, Dr J S Risien Russell and Mr Cuthbert S Wallace, honorary secretary for foreign correspondence Dr Humphry D Rolleston Council Sir Hugh R Beevor, Dr J Vincent Bell Mr C Carter Braine Dr John F H Broadbent Dr John H Bryant, Dr Henry A Caley Mr Albert Carless Dr Edmund Cautley Dr Harry Corner, Dr W J Gow Mr Francis Jaffrey Dr Robert Jones Mr J E Lane Mr John Langton Dr Sidney Martin, Dr H H Mills Dr Frederick S Palmer Mr Walter G Spencer Dr George C Steele Perkins, and Mr H J Waring

Mr **REGINALD HARRISON** opened a discussion on the Perineal and Suprapubic Methods of Prostatectomy No practical subject had occupied surgical attention more than that having for its object the improvement in the treatment of certain forms of prostatic hypertrophy when they occasioned serious obstruction to the natural expulsion of urine from the body The surgical treatment of prostatic obstruction as it occurred in the enlarged or adenomatous gland might he remarked, be discussed under three headings (1) by catheterism alone as practised by the surgeon or the patient himself (2) by perineal prostatectomy and (3) by supra prostatectomy Where the first method sufficed for the wants and comfort of the individual the necessity or expediency for the removal of the prostate did not arise Much more could now be done by strict antiseptic precautions to keep patients within this limit and there could be no question that many had thus been able to enjoy long and useful lives without taking the risk of an operation such as the removal of the prostate entailed Though fully recognising the force of this consideration, which had had prominence given to it by Mr G Buckstone Browne and others there could be no doubt that it was not possible to keep all prostatic cases within these limits On the other hand difficulty in the use of the catheter pain frequent and unrelieved desire, the continued formation of vesical stone in spite of its repeated removal by lithotrity hæmorrhage broken sleep and unrest cystitis and offensive urine in addition to other local and general states of sepsis represented conditions which when persistent no catheter even with its modern accessories could adequately abate It was in c

tatectomy had

Opinions were

cal ility of the perineal and suprapubic methods Perineal prostatectomy had for some years been largely practised both in France and America but hitherto had not found much favour in this country It was Mr Harrison believed, of only limited application and in his practice had been almost entirely confined to some partial removal of the gland For instance by this route pendulous outgrowths of what was known as the middle lobe of the prostate which by acting as a ball valve obstructed micturition, might be dealt with satisfactorily Complete extirpation of the prostate could also be effected by the perineum and many excellent results had been obtained But Mr Harrison had reason to think from cases that had come under his observation that some degree of incontinence of urine was not a very uncommon event after a completed perineal prostatectomy Dr George E Goodfellow of San Francisco[1] reviewing his experience of 73 patients operated upon by him by median perineal prostatectomy had come to the same conclusion and other surgeons had recorded a somewhat similar experience Dr William White[2] of Philadelphia had stated, Past experience does not justify the expectation that the results of prostatectomy by the perineal route will compare favourably with those of total enucleation Turning next to the operation of complete suprapubic prostatectomy Mr Harrison believed it to be the operation of choice in the majority of cases It had many advantages The operation could be completed with a knife aided by the fingers in a very few minutes The bladder and prostate were approached from their most accessible position where there was little

vided free drainage was afforded for as he had pointed out in the Lettsomian lectures of 1888 the density and contractility of the scar left after a complete or partial rupture from violence or laceration of the male urethra were in an inverse ratio to the direct drainage provided for the wound He had never found difficulty or delay in healing after the suprapubic operation provided that the drainage was sufficiently ample Moreover suprapubic prostatectomy had often been the means of bringing to light unsuspected stones contained within saccules and pouches of a presumed healthy bladder Nor was it uncommon to find as age advanced and the prostate enlarged that the obstruction thus caused resulted in pouches in which concretions, small stones, and putrid urine might be detained These considerations were of much importance in determining the precise nature of the operation that should be selected for the removal of the prostate Partial suprapubic prostatectomy was an alternative operation but it had not on the whole proved a success Instances had been recorded where after partial removals in this way the entire gland had had to be enucleated and this had been attended with good results Enucleation with the finger alone as now practised had greatly simplified the process of complete removal and had rendered more secure that which was to some extent a matter of chance In making reference to the distinctions between partial and complete extirpation Mr Harrison did not wish to minimise in any degree the originality of Mr Freyer's work but only referred to the point for the purpose of illustrating the wide difference in results between partial and complete removal of the gland however effected In reference to the mortality attendant upon the two forms of prostatectomy under discussion Mr Harrison was not disposed to think there was much difference in this respect between them including all causes of death it was about 10 per cent probably it was rather less with the perineal operation He had no doubt that this percentage might be considerably reduced in many instances by an earlier prostatectomy and by the exclusion of malignant and other unsuitable cases where the operation had to be undertaken for distinctly palliative purposes

Mr W **BRUCE CLARKE** speaking from his own experience agreed with Mr Harrison that in all ordinary circumstances the suprapubic operation was the best He was very glad it was becoming more usual to operate on cases earlier than formerly The time of operation depended upon the degree and symptoms of obstruction The symptoms varied probably because the gland became congested from time to time The method of enucleation was discussed and the importance of getting into the right layer of the capsule was emphasised. This could not be done by incision through the mucous membrane. Incontinence of urine was, Mr. Bruce Clarke believed, unusual. In respect to the alternative, the perineal, operation there were a few cases in which this operation was justified, and in some cases a combination of the perineal and suprapubic methods might be adopted.

---

[1] Journal of the American Medical Association December 1903

[2] Annals of Surgery December 1904

Mr. W. G. SPENCER (who exhibited microscopic specimens of Carcinoma, Fibrous Hardening, and other diseases of the Prostate) referred to certain cases in which he had found the perineal operation useful. Some were cases of prostatic obstruction and were instances of densely hard prostate without much enlargement, such as the diffuse fibroma of the prostate, from which one of the microscopic sections had been taken. The various histological changes which might produce this condition were discussed and several cases were described in detail and the special methods which Mr. Spencer had adopted for the performance of perineal prostatectomy were described. In such cases of hard prostates it was difficult or impossible to separate the gland from its capsule. Benign lesions of the prostate might become malignant and this was another reason for dealing with the prostate in the manner suggested.

Mr. P. J. FREYER said that no real comparison could be made between the perineal and the suprapubic prostatectomy because they were applicable to such different kinds of cases. The latter was applicable to prostates enlarged to any extent but the former was applicable only to small hard prostates such as the cases referred to by Mr. Spencer. Accidents of various kinds were found after the perineal operation, such as rectal injury, rectal fistula, perineal fistula, orchitis, incontinence of urine, stricture, and loss of sexual power, which did not occur after the suprapubic method. In 110 cases which he had previously recorded the mortality had been about 10 per cent. but in 85 operations more recently performed the mortality had only been 5·5 per cent. This reduction depended on rapidity of operation, improved methods, and improved after-treatment.

Dr. H. T. HERRING remarked that there were four considerations which influenced the decision as to the operation performed—the mortality, questions of drainage, ease of operation, and after-effects. In general terms he recommended the suprapubic method, but advocated more careful preventive methods as obviating the necessity for any operation.

Mr. C. W. MANSELL MOULLIN thought that the choice of operation depended upon the size and condition of the prostate and also on the accessibility of the organ. In stout people it was very difficult to reach the prostate satisfactorily by the perineum but the choice of operation depended also upon the position and size of the enlargement, the kind and degree of the growth, and the question of drainage.

Mr. CUTHBERT S. WALLACE advocated the suprapubic method in most cases as being more satisfactory on general surgical principles. It was important to avoid, if possible, operation in states of active sepsis.

Dr. HEYWOOD SMITH referred to a case operated on suprapubically some time before in which no incontinence had ensued.

Mr. J. W. THOMSON WALKER discussed the limits of the two operations. The perineal operation was only available when the size of the prostate was small and the thickness and the depth of the perineum were moderate. The rapidity of the suprapubic operation was an important matter, not more than about 15 minutes being required.

Mr. JOHN G. PARDOE remarked that the important point to his mind was to be able to determine which kind of prostate could be enucleated. Fixity of the gland was a contra-indication to removal and generally indicated malignancy and he agreed with Mr. Spencer in thinking that such cases were best dealt with by perineal prostatectomy.

Mr. HARRISON replied.

OPHTHALMOLOGICAL SOCIETY.

Histological Changes in Choroiditis.—Results of Birth Injury to the Cornea.—Anterior Synechia of the Pupillary Membrane.—Bjerrum's Method of Testing the Field of Vision —Pulsating Exophthalmos cured by Carotid Ligature. —Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on May 4th, Mr. JOHN TWEEDY, the President, being in the chair.

Dr. LESLIE BUCHANAN (Glasgow) showed a series of lantern slides illustrating Histological Changes in Lesions of the Choroid found after Removal of the Eyes for other Causes. The first was disseminated choroiditis of old standing exhibiting the appearances usually described. The second showed proliferative changes in an active stage affecting the [illegible] and others usually found in sympathetic [illegible] third case exhibited well-marked irregular pigmentation of the choroid with fibro-cellular deposit on the surface of the retinal pigment epithelium, characterised by small black spots surrounded by a lighter areola and due to accumulation of pigment granules in the epithelial cells. The last part of the demonstration was concerned with the formation of the myopic conus which was shown to involve more than a mere stretching of the choroid as in two instances a fibro-cellular formation was found on the surface of the elastic lamina, in the one case vascular and in the other degenerated.

Dr. BUCHANAN also read notes of two cases illustrating Late Effects of Birth Injury to the Cornea. The first case was that of a girl, aged 12 years, with defective vision represented by $\frac{6}{60}$ and $\frac{6}{18}$ in the right and left eye respectively. Superficial observation indicated the presence of a corneal nebula but when examined with the ophthalmoscope and a 12 D. convex lens the appearance was found to be due to two peculiar lines at the posterior surface (refraction opacity), double outlined and altering with the position of the observer. The appearance so closely resembled that observed by Buchanan and Thomson in cases of birth injury that this matter was inquired into and was found to correspond exactly with that described by them in the Transactions of the Ophthalmological Society, 1903. In addition there was a high degree of astigmatism. The second case was similar and in this the astigmatism attracted attention. The corneal scars were so very faint that they were passed over in the first ophthalmoscopic examination. Ophthalmometric measurements were given in both cases and showed that the astigmatism was entirely corneal. The existence of a high degree of astigmatism and the involvement of one eye only should direct the ophthalmic surgeon to investigate the posterior surface of the cornea and the circumstances of birth.

Mr. A. H. H. SINCLAIR pointed out the advantages of Bjerrum's method for testing the visual field in clinical work, especially in the diagnosis of glaucoma. A large screen of black velvet, marked with lines of black thread in a radiating and concentric manner in order to determine the extent of the field in any direction, was employed. The fixation point was in the centre and the test objects of white ivory (1 – 20 millimetres in diameter) were carried across the screen by means of a slender black rod while the field of vision was mapped out by black pins and transferred to an ordinary perimeter chart. The advantage of the method was in obtaining a more discriminating chart of the centre of the field involving relative defects of great clinical importance which were not demonstrable by the ordinary perimeter. Lantern slides selected from a number of charts illustrated glaucoma in which the areas of vision and relative defect were conterminous at the blind spot, this being in all cases partly encircled by a horn-like projection of the area of highest visual acuity. Optic atrophy, on the other hand, though showing an even greater limitation of vision, had not this peculiarity, which was a permanent one, as shown by cases of several years' standing.

Dr. A. J. BALLANTYNE read a paper describing the Microscopic Examination of the Left Eye of an eight months Fœtus in which the pupillary membrane was almost complete and closely adherent at one part to the posterior surface of the cornea, the iris being attached in the same situation. The cornea itself was normal but the endothelial lining of the anterior chamber was almost entirely absent along the line of contact of iris and pupillary membrane with the back of the cornea though present elsewhere. Remains of the hyaloid artery and tunica vasculosa lentis were also present. Dr. Ballantyne attributed the adhesion to an inflammatory process which had led to destruction of parts of the endothelium of the anterior chamber and consequently of an intimate adhesion of its walls at this point, including the iris, the pupillary membrane, and the cornea. He alluded to 14 cases already recorded and discussed the theories put forward in favour of the one he had adopted.

Mr. S. JOHNSON TAYLOR reported a case of Pulsating Exophthalmos cured by ligature of the common carotid. The patient, a woman, aged 55 years, was first seen four years ago suffering from this condition on the right side with a well marked intracranial bruit audible to herself and to the observer with the stethoscope The bruit had appeared immediately after a fall seven weeks before the consultation in which the patient had struck the *left* side of her head against a stone step, rendering herself unconscious for a few minutes and at the same time fracturing her collar bone The proptosis developed gradually four weeks later As the symptoms, severe pain, corneal ulceration, and conjunctivitis, became worse in spite of rest with spare diet and potassium iodide, Mr Taylor ligatured the right common carotid at the patient's own home about nine weeks after the injury, the result being a complete and permanent cure, no untoward effect ever being manifested

OBSTETRICAL SOCIETY OF LONDON

Mortality in Childbed both in Hospital and in General Practice —Repeated Tubal Pregnancy — Gonococcic Peritonitis

A MEETING of this society was held on May 3rd Dr W R DAKIN, the President being in the chair

Dr ROBERT BOXALL read a paper on Mortality in Childbed both in H offered the three death rate from ad and Wales, in Scotland, or in Ireland (where it was abnormally high as compared with the other divisions of the kingdom) but in London it had declined considerably (2) the death rate from accidents of childbirth had declined slightly in each division of the kingdom but was abnormally high in Ireland and in London had markedly diminished and (3) the death rate from puerperal septic diseases had if anything shown a tendency to increase in each division of the kingdom but in London had been declining for at least the last decade In support of these opinions a large amount of statistical material was exhibited chiefly compiled from the records of the General Lying in Hospital York road, London S E The first table showed the deliveries deaths, and death rate in childbed at the York road Hospital for three successive periods—1833 to 1860 1861 to 1877, and 1879 to 1904 During the first of these there were 5833 deliveries with a death rate from all causes of 3 08 per cent during the second there were 3773 deliveries with a death rate from all causes of 1 69 per cent and during the third there were 11 186 deliveries with a death rate from all causes of 0 47 per cent Tables were also exhibited showing the death rate from childbirth from puerperal fever or metria from accidents of childbirth and from all causes estimated for 10 000 children born alive these tables gave the various particulars for London for each year from 1848 to 1903, for England and Wales for each year from 1847 to 1903 for Scotland for each year from 1855 to 1902 and for Ireland for each year from 1864 to 1903 Another table showed the mean mortality from childbirth and from puerperal sepsis and accidents of childbirth in London England and Wales, Scotland and Ireland before 1880 and after 1881 From this it appeared that in London the total childbirth mortality per 10 000 births was 48 5 from 1848 to 1880 and 35 4 from 1881 to 1903, in England and Wales it was 48 7 from 1847 to 1880 and 48 4 from 1881 to 1903, in Scotland it was 49 8 from 1855 to 1880 and 50 0 from 1881 to 1902, and in Ireland it was 66 0 from 1864 to 1880 and 67 1 from 1881 to 1903 In other tables placed side by side for the purpose of comparison there was shown the mortality of childbirth and in childbed at the York road Hospital for the last 25 years and in England and Wales for the years 1901–03 In spite of the large number of serious cases sent to hospital the deaths occurring under the head of accidents of childbirth and from septic disease were less in hospital than in private practice While retaining the douche before delivery and immediately afterwards routine douching during the greater part of the puerperium had been given up, and the later use of the douche took place once only—namely on the fifth day From August to October, 1888, an attempt was made to replace corrosive sublimate by salufer for douching but the results were very unsatisfactory —Dr A L GALABIN expressed an opinion on the conclusion that the death rate from puerperal sepsis had if anything shown a tendency to increase in each division of the kingdom He thought this conclusion too pessimistic and not supported by the charts From statistics which he had himself published he concluded that there had been a distinct improvement in the mortality from puerperal septicæmia in England and Wales since 1880 which for the previous 25 years had been conspicuously absent although it was not so great as might be desired being rather less than half the improvement in septic diseases apart from the puerperium —Dr W S A GRIFFITH said that it was obvious to every consultant that as a rule the disease was neither diagnosed nor was efficient treatment adopted until the patient was hopelessly septic and beyond the aid of successful treatment He thought that some other cause must have been at work to account for the disastrous effects of douching with salufer At Queen Charlotte's Hospital patients were frequently admitted in labour with infective vaginitis and it had not always been possible to disinfect these severe cases in time He asked whether Dr Boxall had met with the same difficulty and, if so how he had so successfully dealt with it —Dr C O FOWLER alluded to the difficulty met with by medical practitioners in controlling the engagement of nurses for confinement cases in private practice He considered that a nurse should never be asked to give a douche unless she had had a proper training He deprecated the practice which largely prevailed of the nurse endeavouring to get the case over before the arrival of the medical man He knew it was a common practice among some of those who ostensibly professed to follow aseptic methods and to disinfect their hands before making a vaginal examination to handle various articles between the disinfection and the examination regardless of the risk of reinfecting them —Dr C J CULLINGWORTH related the circumstances in which on his initiative salufer had for a time been used as a douche and for washing the external genitals He was still in doubt as to whether the occurrence of sepsis just at that particular time was really due to the use of salufer Of course salufer itself could not convey infection and if it was the cause of the outbreak it could only be so indirectly owing to the discontinuance of douching with corrosive sublimate The great value of the paper to his mind was that it once more emphasised the unpleasant fact that whilst in lying in hospitals sepsis had for all practical purposes been eliminated the prevalence of puerperal septicæmia in the country generally was just as great as ever He believed that the great hope lay in the direction of better clinical instruction both for medical students and for midwives He should rejoice if the passing of the Midwives Act had the effect of indirectly calling attention to the conditions under which English medical students obtained their practical instruction in midwifery —Dr C E PURSLOW thought that the great importance of cleansing and disinfecting the vulva of the parturient woman was sometimes likely to be neglected in private practice —Dr BOXALL in reply said that he hoped that Dr Galabin's criticism would prove correct The evidence of the disastrous effect of salufer as a douche rested not on the mortality so much as on the morbidity records as evidenced by the temperature charts This to his mind appeared conclusive and warranted the belief that it would be better to omit the douche altogether than to use with it an inefficient antiseptic He considered that a nurse unless properly trained should never be allowed to administer a douche after delivery In his experience also notification of puerperal fever was rarely made till death was imminent The Notification Act had been practically inoperative in many places so far as puerperal fever was concerned Recognising the futility of attempting to determine the presence of gonorrhœal and of septic matter in the vagina in the case of patients admitted to hospital during labour the practice was followed of disinfecting the vulva and the vagina if possible before delivery and of douching with an antiseptic solution immediately afterwards Under this treatment ophthalmia rarely occurred It was satisfactory to find such a general consensus of opinion among the Fellows of the society as to the necessity of improving the clinical teaching of the medical student in midwifery.

Dr. **PURSLOW** read a short account of a case of Repeated Tubal Pregnancy in which he had operated twice. On each occasion there was intraperitoneal hæmorrhage from the fimbriated extremity of the tube, after the patient had gone exactly a fortnight over the period.—Mr. **ALBAN DORAN** referred to a case in his own practice which had symptoms of tubal abortion on the right side and in which he operated a year later for tubal gestation on the left. He then found evidence of the former pregnancy.—Dr. **HERBERT R. SPENCER** said that he had operated on three cases of repeated tubal pregnancy, although he did not usually operate in early tubal gestation.

Mr. A. G. R. **FOULERTON** showed Microscopic Specimens from a case of Acute Peritonitis in which cultures of the micrococcus gonorrhœæ had also been obtained from the peritoneal exudation. The tubes and the ovaries of both sides were removed by operation. The micrococcus gonorrhœæ was found in the vaginal discharge and also in pure culture in the pus contained in the tubes. Histologically, the lining epithelium of the tubes showed but little change and a careful examination had so far failed to show any penetration of the gonococci either into the epithelial cells themselves or below the epithelial lining. He thought that infection of the peritoneum had been brought about by an acute kink near the middle of the right tube. The ostium abdominale of the left tube was apparently closed.

HUNTERIAN SOCIETY.

Discussion on Influenza.

MEETINGS of the Hunterian Society were held at the London Institution, Finsbury-square, on March 22nd and April 26th, when there was a discussion on Influenza, Dr. F. J. **SMITH**, the President, being in the chair.

The discussion was opened by Professor T. **CLIFFORD ALLBUTT** who reminded his hearers that he well remembered the outbreak of the epidemic in the "forties" and that he had heard something of the manner in which people suffered during the previous epidemic in the "thirties." Since those dates there had been epidemics but none that showed anything like the severity of the outbreak which commenced at the end of 1889 and the beginning of 1890. He reminded his hearers that influenza had been known fairly definitely from the twelfth century onwards. Having traced the course through the world of the 1889 epidemic he passed on to consider the contagious nature of the infection. Although contagion was now assumed as obvious this was not the general opinion in 1890, and Professor Allbutt gave examples from his experience as a Commissioner in Lunacy when he was able to observe the course of influenza in the lunatic asylums in England. Those persons who were in contact with the outer world—viz., the medical and domestic staff and the persons visiting them or the patients—were attacked at the rate of about 50 per cent. but on the inmates themselves, those who did not go out in the outer world, the incidence of the disease was relatively slight. Professor Allbutt then said that in his opinion the disease was propagated in the sputum and the spray from the respiratory tract and that unless a patient had respiratory affections he was not infectious. The speaker went on to point out that, like pulmonary tuberculosis, influenza might cause excavation of the lungs. Continuing his address, he passed on to consider the various symptoms, laying great stress upon the extreme suddenness with which influenza, as a rule, attacked its victims. The suddenness of the onset was often, he said, a useful point in the distinction between influenza and typhoid fever. As to treatment he said that it would be dealt with by other speakers and he himself was glad not to have to deal with that particular subject because he did not know that there was anything which could be called specific. Two points, however, he wished to impress upon them (1) that the patient ought to do what nobody, as a rule, would do—that was, go to bed at once and stop there until the acute phase was well passed; and (2) that during the long convalescence he would recommend what he might call a non-toxic diet—viz., milk, custards, and no meat.

Dr. H. **FRANKLIN PARSONS** gave an account of the epidemiology of the disease.

On April 26th Dr. W. **BULLOCH**, in discussing the bacteriology of the disease, said that the researches of bacteriologists culminated in 1892 with R. Pfeiffer's discovery of the hæmophilic microbe since known as the bacillus influenzæ. Practically no new facts have been added to Pfeiffer's original discovery. After searching trials he (Dr. Bulloch) had found that the bacillus only grew in the presence of hæmoglobin and that it was difficult to preserve the cultures alive. The important practical point in reference to Pfeiffer's bacillus was its parasitic character which rendered its cultivation a matter of difficulty. It was very susceptible to drying—a fact which altogether negatived the supposition that influenza was carried to great distances by the air. The extreme temperatures at which the bacillus grew were 27° and 42° C. This showed that in temperate climates, at any rate, the microbe did not multiply outside the body of man. Influenza was a highly contagious disease and in almost all cases it was propagated directly from man to man. As Pfeiffer showed, the bacillus influenzæ was found locally in the respiratory passages and it was an extreme rarity to find it in the circulation. Dr. Bulloch then emphasised the fact that whereas in the early "nineties" Pfeiffer's bacillus was frequently met with it had in recent years become much rarer although epidemics of catarrh—described as influenza—were still very prevalent. He (Dr. Bulloch) believed that what was called influenza clinically was not one disease but probably a series of diseases caused by different microbes among which a prominent place had to be given to the micrococcus catarrhalis and allied cocci. He then referred to the spread of these catarrhal diseases and emphasised the importance of the researches of Flügge and his assistants on the dissemination of microbes in droplets in the form of spray discharged from the mouth and nose during coughing, sneezing, &c. He then referred to the important question of immunity. Experiments on animals and observations in man showed that the immunity, if it existed, was of low degree and at the same time of slight duration. In all probability, however, some immunising influences were at work as in the course of time the microbe became attenuated. The continued occurrence of epidemics of influenza was referable to the fact that the microbes could persist for long periods in the respiratory passages of people who had had the disease. With a disease so eminently contagious, and considering the innumerable chances of infection and the general disposition of man to the disease, a satisfactory prophylaxis was almost impossible.

Dr. T. **GLOVER LYON**, in discussing the clinico-pathology of the disease, said that the most striking feature of influenza was the multiplicity of symptoms and the variety of combinations of them in different cases. He believed that the poison affected all the tissues of the body but chiefly those in a bad state of nutrition; in other words, the weak points. It attacked specifically the central nervous system and might well be named centro-neural fever. In slight cases the symptoms were referable alone to these organs and in more severe cases the nerve centres modified the symptoms displayed in other parts. An important condition sometimes arising was vaso-motor paralysis, especially of the lungs, producing intense congestion. This sometimes proved fatal and had been noticed by Graves. There had been a real change in the disease within record, so much so that old physicians who had seen the epidemic of 1847 did not at first recognise the disease in 1889. In descriptions written before 1889 the respiratory symptoms were made most prominent, then the nervous, the gastro-intestinal coming last. In 1889 the nervous symptoms were most striking, then the respiratory, and lastly the gastro-intestinal. In 1892 and since the gastro intestinal had equalled, if not surpassed, the respiratory symptoms in importance, the nervous symptoms still remaining in the first rank. He thought this change was accounted for by modifications which had taken place in our mode of life since 1847. Between 1847 and 1889 the strain upon the nervous system had been very much increased by the introduction of railways, telegraphs, &c. He believed, too, that of late years the feeding of our population had much deteriorated. Instead of plain food, well cooked, eaten leisurely and regularly at home, many people now took food hurriedly and irregularly in restaurants. Hence, a greater strain had been put upon the digestion, accounting, he thought, for the increased prominence of gastro-intestinal symptoms (and in parenthesis of the increase in appendicitis).

Dr. J. **FORD ANDERSON** said: I only wish to refer to one of Professor Allbutt s remarks and that is as to the special infectiousness of the catarrhal form of influenza That is not quite my experience I am quite willing to admit that the catarrhal form of influenza is the most infectious but I cannot doubt the evidence with regard to the infectiousness of the other forms too, at least in every case where there is a rise of the temperature, and I think that is the best guide Where there is an elevation of the temperature the disease inevitably goes through the house I have seen this both in the gastro intestinal and in the nervous forms I have had reason to think that treatment by sprays is a preventive I have used resorcin for spraying and quinine for gargling, and certainly the members of a family in which these have been used seemed to escape better than those in which they were not employed I have also found good results from the use of quinine giving three grains three times a day or as much as the patient could stand In that case the patient has been apparently immune from the disease With regard to treatment—because I am taking the practical side—I should like to say that although I use the salicylate of sodium I distrust it It is so depressing and upsetting to the digestive organs and I generally prefer salicin as introduced by Maclagan in 20 grain doses, with the addition of phenacetin to reduce fever and to calm the nervous symptoms But the sooner we get away from those antipyretics to quinine the better Quinine however does not seem to me to suit cases of broncho pneumonia at all There I always go to digitalis chloride of ammonium and nux vomica which I think are invaluable in broncho pneumonia I think the digitalis is a most important element It increases the tonic contraction of the ventricle and that is all right but sometimes the arterioles are contracted and unless they are dilated by *some means* there will be trouble and there will be an increase of the broncho pneumonia For that I think the addition of the nitrite of sodium or trinitrine is effective in removing the patches of broncho pneumonia I should like here to express the great benefit I have received from the use of Hill and Barnard s sphygmometer To sum up I think it is a ques

treating the symptoms keeping the patient the amount of fever, *patient There is no panacea for* the disease either in diet or in medicine

Mr F ROWLAND HUMPHREYS followed and spoke with special reference to the cardiac complications of the disease

Mr JOHN ADAMS, arguing from his own experience and from many similar cases considered that though influenza showed marked attenuation in the majority of cases yet others occurred which exhibited no diminution in severity of the symptoms

Dr ST CLAIR B SHADWELL said There was one point mentioned by Professor Allbutt on the last occasion with regard to angina pectoris which I should like to mention He said he thought that it was not the heart but the aorta that was affected But I think after all the cases of angina pectoris that we find in influenza even in very severe cases are essentially nervous and of neurotic origin One case that I saw was very marked A patient who had had an attack of influenza for three days called me in to see her She had attacks which were remarkably like those of angina pectoris I treated her with nitrite of amyl which gave some relief But on the third morning I was sent for and she was then very bad indeed she sat up in bed she gasped for breath she became livid her hands and feet were cold and I thought it was a genuine case of angina pectoris I examined her very carefully and while examining her chest I happened to press my finger on one of the intercostal spaces, she flinched I was quite acquainted with the cases of intercostal neuralgia which we meet with in influenza Consequently I left the chest and went to the back and ran my finger down the spine, the patient called out with pain Then I knew exactly what was wrong it was a case of spinal influenza if I may so term it—that is a case of influenza in which the posterior root of a spinal nerve is affected I have known such cases for many years now What I did was this I took a blister and put it on the tender spot and the patient never had another attack of angina pectoris, she was perfectly cured *That was some years ago* I have attended her for some slight ailments since but she has never shown any symptoms of heart trouble In many cases of neuralgia coming on after influenza if you examine the spine you will find an acutely tender spot and if that tender spot be treated with a blister the pain is relieved in 24 hours or less and in two or three days the neuralgia or the neuritis is practically cured beyond a little tenderness of the nerve I think cases of angina pectoris which are met with in influenza are essentially neuroses and are not due to any cardiac conditions

The PRESIDENT concluded the discussion by a few remarks upon points raised therein He expressed his opinion that in the treatment of influenza the wishes of the patient should be specially considered and finally offered the thanks of the society to all those who had attended to take part in the discussion

---

EPIDEMIOLOGICAL SOCIETY —A meeting of this society was held on April 29th, Dr B A Whitelegge, the President being in the chair —Dr G S Buchanan read a paper on the Spread of Small pox around Small pox Hospitals in Relation to Aerial Convection So long ago as 1886 Mr W H Power published his report to the Local Government Board on the Incidence of Small pox in London from 1876 to 1885 and in 1884 the subject of hospital influence was brought before the society by Dr J C McVail but in the six years following the question fell into neglect owing to the absence of epidemics During the last four years however the recurrence of outbreaks had necessitated the establishment of hospitals and revived the interest in their influence Mr Power had shown in respect of Fulham Hospital that there was a regular graduation in the incidence of the disease around the hospital the cases being most numerous among equal populations or numbers of houses within the quarter mile radius and fewer in each successive zone of half three quarters and one mile In 1884 notwithstanding new and stricter precautions the experience of 1881 was repeated and the acute cases had since been *sent to the ships in the Long Reach and the* milder cases and convalescents to Gore Farm, Darenth In the next epidemic of 1901–02 the same course was followed so that the cases on the ships averaged 164 and reached a maximum of 275 and while the average incidence in London was 2 per 1000 (the highest that in Holborn being 7 2) it was 16 in Grays and 18 5 in the 12 parishes of the Orsett union Purfleet suffering most severely yet Dr J C Thresh Dr Buchanan and Mr R Corbet could not discover intercourse with *the ships or neglect of revaccination* of disinfection or of isolation A number of unvaccinated infants succumbed early but there was not the wholesale loss of life that at Gloucester resulted from persistent neglect The sanitary staff worked well and there was no concealment of cases Even contacts played no important part no case occurring among them in four fifths of the houses attacked Yet throughout the epidemics Purfleet Grays, and West Thurrock suffered far beyond the remainder of the district On the Kentish shore a large *number of* workmen were employed in erecting a temporary hospital on the uninhabited flats During the three months Dec 1st, 1901, to Feb 27th 1902 before any patients had been received, cases of small pox appeared among them from time to time 60 in all though of course, personal communication between these men and the members of the staff could not be excluded This however could not account for the appearance of cases on board vessels that had anchored in the *Long Reach when 12 days later they were* at Rochester Faversham or other ports In studying Dr A K Chalmer s report of small pox at Glasgow in 1890 97 the reader was struck by the disproportionate incidence on the eastern district where was the Belvidere the only hospital In whichever division the disease broke out the hospital had no sooner begun to fill than the number both absolute and relative of cases in the eastern division rose until they in three of the six years exceeded and in three closely approached *the highest in the other wards* He admitted that from the reports of the 600 cases of small pox at Manchester from 1902 to 1904 he could draw no conclusion for the population of 48 000 living within a mile of the hospital contributed no more than 25 cases and none of the men employed in laying drains around the hospital were attacked though they refused to be vaccinated Dr R J Reece s report on the epidemic at Liverpool in 1902–03 was the most important contribution *to* the question that had appeared of late With a population of 720 000 there were in the two years 1902 and 1903 not counting those brought by shipping 2278 cases in 1632 houses There were two old hospitals, Priory road and Park hill and one new one, which alone had been approved and aided by the Local Government Board at

Fazakerly outside the city boundary. For 53 weeks Priory-road was the only hospital, when that at Fazakerly was added and remained so to the end, Priory-road being closed after 77 weeks' occupation, while the Park-hill hospital opened during the height of the epidemic was used for 24 weeks only. Park-hill was opened on Jan. 12th to meet a local outbreak due to an unnotified and fatal case. The houses newly invaded within a mile of this hospital rose from two to four in each successive fortnight to from 20 to 50 and the district continued to suffer more than the rest of Liverpool until the hospital was closed. The graduated incidence shown by the percentage of houses attacked in each zone around was well marked, as it was also in those around the small hospital at Priory-road. In what did this "hospital influence" consist? He denied that the traffic of ambulances and vehicles, the visits of friends or tradespeople, or the movements of the staff sufficed, whatever influence was allowed them, to explain the graduated incidence. Save at Dewsbury and a very few places of less importance no general violation of the rules or breaches of regulations for seclusion of patients had been established and the patients, staff, and tradesmen were not drawn from the immediate neighbourhood more than from more or less distant quarters, while ambulance traffic would follow the lines of the main roads, not the smaller streets and alleys. Felling was invaded from the side of Gateshead hospital which stood in a high open position, its own hospital being two miles on the other side of the town. The negative character of the evidence from Manchester was explicable by the measures adopted by Dr. Niven to prevent the diffusion of the epidermis. Then the diffusion of dust, chemical and other, from factory chimneys and of acid sprays which carried by air-currents were seen to fall on certain areas leaving others, of pollen grains, volcanic ashes, and experimentally the spores of moulds and bacteria, all showed the reasonableness of the hypothesis which sufficed to explain nearly every instance of the spread of the disease from a hospital whether other hypotheses did so or not.—Dr. C. B. Ker admitted that Dr. Buchanan's paper was the best defence he had heard of the aerial theory and would have convinced him if he had not known that all evidence on the other side had been suppressed. The supporters of human agencies did not demand that infection should be always, if ever, conveyed by winds but they did demand some evidence of such convection when all the conditions were favourable. The sole isolation hospital in Edinburgh was badly placed and ill-arranged in every way, only 72 yards distant from the fever block with 400 patients, 325 yards from the poorhouse with 1000 inmates, nearer to a hydropathic establishment for 200 patients, while paupers worked all day close to its boundaries. The average number of patients in the small-pox hospital had been 55 for two months and 47 for three months. Within the quarter-mile circle were Craig House Asylum with 400 patients and a general population of 2000, but the only cases within a mile of the hospital were two imported and two secondary in the poorhouse, and by a curious coincidence exactly the same occurred in another poorhouse far away. The fever patients were mostly vaccinated but a large number of typhoid fever patients and of cases of erysipelas in the ward nearest to the small-pox block were not, yet not one contracted the disease. The nurses for the small-pox wards were volunteers from the fever hospital and only the most trustworthy were accepted. Once in they were never allowed to leave the building on any pretext, while Dr. Ker, the medical officer of health, the Local Government Board inspector, and the ambulance attendants were the only persons who were admitted. Here was the secret of their success. He considered the association of fever and small-pox hospitals to present many advantages; the old nurses were more to be trusted than new recruits and the proximity of the hospitals enabled him to exercise more control. Just outside the mile limit several houses were invaded but in three of the first four exposure to infection was proved. The actual epidemic was concentrated around the site of the old hospital which in previous epidemics used to be blamed as a centre for diffusion of disease in the district.—In view of the lateness of the hour and the importance of the subject further discussion of the paper was at the instance of the President adjourned to the following Friday.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on April 26th, Mr. W. B. Holderness, the President, being in the chair.—Dr. W. F. Lloyd showed a child, aged ten years, suffering from symptoms pointing to Syringomyelia.—Dr. R. H. Cole read a paper on the Clinical Aspects of General Paralysis. He based his remarks on the experience gained from the treatment of 19 consecutive cases in private patients, of which careful records had been made. He dilated on the variability of the premonitory symptoms and the difficulty of early diagnosis, also the necessity of placing most cases as speedily as possible under supervision and control. The age incidence in the cases narrated averaged 44 years, the disease affecting twice as many married as single persons. The disease lasted from a few months to a period as long as seven years, although most cases proved fatal in two and a half years. He pointed out the rarity of the disease in female private patients, [illegible] the number. The different types [illegible] described and special reference was made to the tabetic forms. The ocular signs and the cerebral seizures in the various cases were also detailed. The etiological factors were next discussed and it was stated that the element of syphilis was sufficiently proved in 65 per cent. of the cases. Some lantern slides kindly lent by Dr. F. W. Mott illustrating various points in the pathology of the disease were exhibited.—Mr. W. J. Handfield Haslett thought that the question as to the causation of general paralysis by syphilis was not so definitely settled as they would gather from Dr. Cole's remarks. It was, he said, at least strange that a disease like syphilis should at one time bring about a definite train of symptoms compatible with considerable longevity and at another a fatal disease like general paralysis. With reference to the fact alluded to by Dr. Cole, that such a large proportion of sufferers were married men, Mr. Haslett offered the explanation that the early mental symptoms of general paralysis were all of a nature directly calculated to predispose to matrimony and, in fact, he was of opinion that many general paralytics married in the early stage of the disease. And, finally, since it was in the early stage of general paralysis that so much social misery and unhappiness were brought about, Mr. Haslett asked Dr. Cole whether he would give an account of what he considered the earliest signs of the disease. He himself was inclined to attach great importance to the eye symptoms, particularly to the loss of the ciliary reflex.—Dr. Cole having briefly replied the proceedings terminated with a vote of thanks to Dr. Cole for his interesting contribution.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—An ordinary meeting of this society was held on May 1st, Dr. Thomas Barr, the President, being in the chair. A discussion upon Vertigo was opened by Sir Victor Horsley and Dr. J. S. Risien Russell. Sir Victor Horsley confined himself to cases of vertigo arising from destructive ear disease or new growth and discussed minutely the symptoms which enabled the lesion to be localised. In disease of the semicircular canals he compared the sudden onset to that of an epileptic fit or an attack of trigeminal neuralgia and pointed out that this was due to a summation of stimuli. When the lesion was in the neighbourhood of the medulla it was almost impossible to distinguish the site of the growth. As regarded symptoms, they had to consider both *rotation* and *titubation*, the latter occurring when the lesion was anywhere between the medulla and the cerebral cortex. The results of observations occurring when rabbit shooting were valuable in localising lesions of the pons and crus. The experiments of Mills of Philadelphia showed that the centre for orientation was situated in the temporal lobe of the cerebrum and patients with growths in this region showed titubation cured by removal of the neoplasm. Sir Victor Horsley's address was illustrated by lantern views.—Dr. Risien Russell discussed vertigo as a symptom in affections of the ear, in organic intracranial disease, in disseminated sclerosis and tabes, in epilepsy, neurasthenia, and hysteria. He pointed out the difficulties in diagnosis, the most trustworthy data upon which a correct diagnosis could be established, and the influence of diagnosis on prognosis and treatment.—Dr. J. Dundas Grant, Dr. H. Tilley, Dr. Urban Pritchard, Mr. R. Lake, Mr. E. B. Waggett, Mr. Hunter F. Tod, Mr. G. W. Hill, Mr. Hugh E. Jones, and the President took part in the discussion which followed.

MEDICAL DEFENCE UNION.—The annual general meeting of the Medical Defence Union, Limited, will be held at the Medical Society's rooms, 11, Chandos-street, W., on Thursday, May 25th, at 5 P.M., to receive the annual report for 1904, and to discharge other business.

Reviews and Notices of Books.

Health at School, considered in the Mental, Moral, and Physical Aspects. By CLEMENT DUKES, M.D., B.S. Lond., F.R.C.P. Lond., Physician to Rugby School, &c. Fourth edition, revised, enlarged, and illustrated. London: Rivingtons. 1905. Pp. 606. Price 10*s.* 6*d.* net.

THOSE who are already acquainted with previous editions of Dr. Dukes's book, the last of which appeared in 1894, will welcome the publication of a new edition. For the sake of those who are not so acquainted with it we may point out that it is not a mere dry treatise upon drains and ventilation, upon infection and isolation, upon wearing flannel next the skin, and eating porridge for breakfast. All of these matters are indeed contained within this volume but there is much more besides. Dr. Dukes considers from the point of view of health practically every side of a boy's life at school—*votum, timor, ira, voluptas, gaudia, discursus*—and is thus enabled to produce a book which affords most interesting reading to all who are concerned in the happiness and the well-being of boys and girls. Even such a matter as the value of compulsory Greek comes within the writer's purview. And here we cannot help recalling a "tag" of equally compulsory Latin, containing the advice *ne sutor ultra crepidam;* for on a purely educational subject such as this Dr. Dukes speaks with no more authority than any other intelligent observer, and a tendency to stray into such by-paths rather detracts from, than adds to, the authority with which he deals with matters upon which his words have real weight. However, with the gist of his opinions even on this thorny subject we can heartily concur, amounting as they do to the doctrine that mentally as well as physically boys and girls vary and that what is mental food for one may be indigestible when supplied to another. We hope that educational authorities may in the future hit upon a plan which will enable masters first to ascertain their pupils' bent and then to arrange their studies accordingly. After the acquirement of the three R's we would not have either compulsory classics or compulsory science for all alike, though there is a certain modicum of general information which must be possessed by all who aspire to escape the charge of illiteracy.

With regard to the choice of a school Dr. Dukes points out that probably the healthy boy coming of a sturdy stock will flourish in any locality, given conditions of ordinary sanitation, but that the delicate boy must have his school carefully chosen for him on the grounds of health as well as of social and educational advantages. He also rightly remarks that many schools at the present day charge first-class fares for third-class accommodation, especially as regards the sleeping and living rooms for the boys. This is a matter into which parents must inquire and insist upon getting proper value for their money. But we fear that at present they have very inadequate notions as to what constitutes proper conditions for school life. We hope that Dr. Dukes's book will be so widely read as to spread abroad more enlightened ideas. Indeed, it is not only at school that the best sanitary conditions are to be provided for growing boys and girls but also at home. The holidays should be, it is true, periods of rest and home influence but they should not be devoted to indulgence in such unhealthy amusements and pursuits that the children go back to school in anything but a satisfactory state of health. Studies, too, must be regulated with due attention to the physical condition of pupils. It is well to remember that the period of most rapid growth does not coincide in boys and girls, being greatest in boys about the sixteenth year and in girls at an earlier age—namely, from 12 to 14. Dr. Dukes quotes some interesting tables showing these variations.

With regard to the arrangements for sleeping accommodation at school, Dr. Dukes is much in favour of large dormitories as opposed to cubicles or separate rooms. We cannot help thinking that it is impossible to lay down any general rule in the matter which shall be applicable to all schools. Much must depend upon the age of the boys concerned and especially upon the relative admixture of different ages. The same criticism may also be applied to the advice that the boys should have little or no leisure time entirely to themselves but should be expected to join in organised games whenever they are out of school. Surely it is better for elder boys to have opportunities of gradually accustoming themselves to find occupation for their leisure moments while they are at school than that they should after a time of exaggerated tutelage suddenly find themselves at a university or in business where no supervision is exercised over their spare time. Dr. Dukes's advice is no doubt excellent for schools containing small boys and probably for the junior classes at a public school. We seem, however, to have a recollection of a certain public school at which some such supervision as he suggests was carried out during every minute of the boys' time and we do not think that the results achieved were in any respect better than those of other institutions which pursued what we have always regarded as the more English plan. It is well for boys to feel that they are trusted; they will then grow up trustworthy.

The last point upon which we will quote Dr. Dukes's wise advice is that of punishment at school. He rightly urges that expulsion should be reserved as a last resort in the case of boys who prove themselves incorrigible by other methods; a boy who loses his character at school should have the opportunity of redeeming it there. On the other hand, corporal punishment of suitable kind in suitable cases is needful and salutary. But the method adopted must be suitable. It is becoming recognised that "boxing" the ears is cruel and dangerous and Dr. Dukes insists on the further danger of shaking. Against the birch there is nothing to be said if applied with discretion and to the proper region.

In conclusion, we can only express the hope that the new edition of this book will be carefully studied by the greatest possible number of both parents and schoolmasters and that they may unite to put into practice the many excellent pieces of advice which it offers for their guidance.

Transactions of the American Ophthalmological Society. Fortieth Annual Meeting, held at Atlantic City, N.J., 1904. Vol. X., Part II. Hartford: Published by the Society.

THIS number of the Transactions contains reports of 28 papers read before the society, of which the chief are: 1. Operations upon the Eyeball in the presence of an Infected Conjunctival Sac, by Dr. O. S. Bull. It is shown in this communication that a conjunctival sac free from noxious bacteria of all kinds does not exist. Quoting from Rymowicz, who examined 100 healthy eyes, it appears that in 94 cases the bacillus pseudo-diphtheriticus was present; in nine the pneumococcus, in five a streptococcus, in six the Morax-Axenfeld bacillus, in six the staphylococcus aureus, and in eight cases the staphylococcus albus. Dr. Bull strongly urges the importance of thoroughly freeing the conjunctival sac as well as the margins of the lids from the various germs always present by careful irrigation with some indifferent fluid, such as normal saline solution, and to avoid operating as far as possible until the sac and the lids are clean. He is of opinion that if there be suppurative disease of any part of the lacrymal passages all operations on the eyeball are positively contra-indicated. The lacrymal sac must be excised by the galvano-cautery and the lacrymal puncta obliterated. 2. Dr. G. E. de Schweinitz contributes two papers, one on Certain Non-traumatic Perforations of the Macula Lutea, and a second on Conjunctivitis Nodosa. Each article is accompanied by a coloured plate and the latter one by two plates in addition, representing the pathological conditions present. Dr. W. C. Posey describes cases of Tuberculous Growths on the Iris and in the Choroid and gives drawings showing the pathological appearances under the microscope, and Dr. Thomas R. Pooley also gives a case of Conglomerate Tubercule of the Choroid. Dr. W. A. Holden describes a case of Mind Blindness, unique in that the entire mesial surface of both occipital lobes and both optic radiations were preserved. Dr. A. Duane gives the results of his experience on Prism Exercises. Besides the above the Transactions of the fortieth meeting contain several interesting papers, as those of Dr. George Gould on Dextrocularity and Sinistrocularity; of Dr. Lucien Howe on the Muscle of Horner and on the Act of Winking and its Photographic Measurements; and of Dr. Robert Sattler on Sympathetic Neuro-retinitis and on Angelucci's Modification of Cataract Operation. There are also several accounts of particular cases, such as that of Dr. F. H. Verhoeff on a rare tumour arising from the pars ciliaris retinæ, which he terms a terato-neuroma; of Dr. Clarence Veasey on a case of Bitemporal Hemianopsia; and of Dr. C. W. Cutler on Symmetrical Enlargement of Parotid and Lacrymal Glands. There is a report of the committee on Standard Test-types which is of value, and Dr. William and Dr. Archibald G. Thomson record improvements in the refractometer which they have devised.

Le Béri-béri: Définition, Etymologie, Historique, Bactériologie, Symptomatologie, Pathogénie, Pathologie Expérimentale, Traitement. Par le Dr. H. VIVIAN DANGERFIELD. Paris: A. Maloine. Pp. ccxlii.-211. Price 12 francs.

THIS comprehensive work on beri-beri has been written with the purpose of dispelling the various confusing ideas on the subject which are at present extant. The several opinions as to the nature of the disease have been grouped and classified in order of seniority, the theories of the pathogeny have been reduced to order, and an attempt has been made to elucidate the two capital points of the malady—viz., its genesis and its essential nature. The results of the personal researches extending over seven years without interruption are detailed and an attempt is made to assign it to its true place amongst the various tropical diseases.

Beri-beri is depicted by the author as a tropical, infectious, contagious, and epidemic disease, characterised occasionally by the presence in the blood of pathogenic germs belonging to the family of cocci—viz., the micrococcus of beri-beri. Clinically the malady appears under three forms, the œdematous, the paralytic or dry, and the mixed. The first two are not distinct maladies but are merely stages of the same morbid process, whilst the mixed form demonstrates this fact. The post-mortem appearances likewise testify to this fact. The author maintains that the view commonly held as to the endemic character of the disease is not correct; its characteristic is really epidemic. The views of various authors concerning its essentials are next narrated, from those of Corre down to the most recent opinions of Hamilton, Wright, and Durham. A good *résumé* of the history of the disease from the seventeenth century to the present day follows, succeeded by an account of its geographical distribution, from which it appears that it flourishes between the 35 degrees of north and south latitude.

In describing the etiology of the affection the author considers the causes under the two heads of those in relation to the sufferers and those in relation to the malady itself. As regards the former he states that age plays no predisposing part: he has found beri-beri at all ages from the youngest to the oldest. As regards sex the evidence of certain authors points to the female being the most affected, of others to the males, but all are struck with the gravity of the disease amongst pregnant women, especially as regards the nervous and cardiac lesions and the œdema of the external genital organs—indeed, the latter may present an obstacle to delivery; one case is mentioned by the author where the orifice of the vagina was reduced to the size of a two-franc piece. There is no predisposition shown by any particular profession or class of society, although some writers state that those who follow sedentary occupations are more liable to attack. Poverty or the reverse merely acts by means of the more capable resistance to the disease offered by the well-to-do. All debilitating causes predispose to the affection. Heredity plays no part. As regards race this malady has been observed in all nations living in the inter-tropical zone. Next with reference to alimentation, many observers have been struck by the persistence of digestive disturbances in beri-beri and so have concluded that the disease had an origin of an alimentary nature: others to-day hold that the latter has a more subordinate influence and plays but a secondary rôle. Thus Manson cites an epidemic in a prison at Singapore, in which the males were decimated and the females were spared, although both had the same food and water. Temperament has no influence, nor has the soil, the air, or the water. Finally, as regards climate, very cold or very hot ones are not favourable for the appearance of the disease. In climates with cold and hot months beri-beri generally breaks out epidemically in the latter, and where there are two seasons, a dry and a rainy one, and in addition where it is hot all the year round, the disease chiefly affects the rainy season.

With regard to the etiology in relation to the malady itself the capital determining factor is infection. The causes favouring the multiplication of the germs, and thus the expansion of the disease, are the following. Heat plays an important rôle; light, electricity, and magnetism also add their influence. Cold acts most powerfully in producing profound modification of the disease which cannot exist in cold climates. A temperature of 0° C. for a few hours can destroy all vitality in the germs. For the latter to develop heat, moisture, and a feeble electrical tension are absolutely necessary, these factors being here enumerated in the order of their importance. The fact of epidemics occurring on board ships after they have left port for some time is explicable by the artificial production of a suitable environment from the fouling of the air in the cabins and the holds of the vessel and the raised temperature in the latter. It is to be noted also that a continued repetition of infection is necessary for the establishment of an epidemic of beri-beri. Another noticeable fact is the readiness to contract the disease shown by wounded men or those suffering from tropical ulcers when they are associated with patients affected with beri-beri. Lastly, the aggregation of human beings creates a medium especially favourable to an outbreak.

Dr. Dangerfield next deals with the bacteriology of the disease. A short history of the various micro-organisms which have been held to have a causative relation to the disease is first given, commencing from the work of Rogers, Ogata, Lucenda, Cornelissen, and Sugenoya. In 1898 Professor Nepveu described a strepto-bacillus. Pekelharing, d'Atchni, and Winkler next narrated the presence of cocci which when inoculated into animals reproduced the symptoms of the disease. Dr. Dangerfield in 1899 discovered certain spherical organisms which were a little larger than pus cocci. Their cultures, however, were sterile. He next introduced certain modifications in the bacteriological technique appropriate for examination in warm climates and used for his researches a modified Jensen medium. The *micrococcus beribericus* discovered by him has certain morphological characteristics which, however, vary according to its stage of evolution Five such stages are enumerated , thus there is a hemispherical, a diplococcic, a micrococcic, a zoogloeic, and finally, the stage of sporulation The cocci show one peculiarity—viz , that in the centre of the preparation they preserve their individuality, whilst at the periphery they come together with a highly coloured conglomeration forming a sort of barrier to the entrance of the colouring agent The characters of the micrococcus and the colouring agents best adapted to display it are fully described, the author preferring one of gentian violet, methyl blue, dahlia violet, kristal violet, methyl green, and alcohol Next follows a description of the characters of the culture The bacterium is essentially aerobic , its chemical and physical reactions are narrated This section on the bacteriology of the disease is very complete , the author concludes that the organism which he has described has its own special and peculiar characteristics and it is highly probable that it possesses either a specific pathogenic effect or an actively associating role

The symptomatology of the disease is next dealt with under the heads of the Period of Incubation, the Period of Invasion, and the Period of Recovery or Death During the first there are a loss of sensation and feebleness of the lower extremities, with an epigastric uneasiness and various symptoms of dyspepsia The period of invasion is characterised by digestive, nervous, muscular, trophic, circulatory, respiratory, and urinary troubles During the period of reparation the symptoms gradually abate Death may be sudden or may occur slowly If sudden it will be from embolism or syncope, if slowly from asphyxia An excellent chapter on the diagnosis of the affection is given and then the means whereby prophylaxis may have a good result are narrated The immediate methods consist in the vigorous application of the measures advocated by the Conference of Venice The more remote methods are the cleaning of the dwellings and localities which have been contaminated, burning of the bodies of those who have died from beri beri, and the undertaking of thorough sanitation in the effected localities

The remaining part of the work is occupied with the post mortem results , the prognosis, duration, and course of the affection , the statistics of its mortality , and the treatment With regard to the last it is acknowledged that at present we have no specific but the author thinks that the secret of success in this direction is likely to lie in a method of serum therapy that is as yet to be discovered An account of the experimental pathology undertaken by Dr Dangerfield and a valuable series of personal observations from 1897 to 1904 complete the volume, which is without doubt the most comprehensive work on this serious disease that has yet been published

---

A *Treatise on Bright's Disease and Diabetes* By JAMES TYSON M D Professor of Medicine in the University of [illegible] Ophthalmology in the University of Pennsylvania, Ophthalmic Surgeon in the Philadelphia Hospital London Rebman, Limited 1904 Pp 381 Price 17*s* 6*d*

THE first edition of this work was published in 1881 and having been out of print for many years it has been in a large measure rewritten and much enlarged The earlier sections of the book deal with the anatomy of the kidney and with albuminuria The remarks on the source of albuminuria and the mechanism of its production are brief and incomplete, the vexed question of "physiological" albuminuria being scarcely touched upon A good account, however, is given of the various forms of casts which may be met with in the urine, together with a consideration of their nature and clinical significance A section has been added on Acute Interstitial Nephritis which is defined as "an acute inflammation of the kidney characterised by a non purulent cellular exudate associated with degeneration of the epithelium but not dependent upon it " The undoubted existence of this form of nephritis as a pathological entity has only been recognised within comparatively recent years, although the first case was described by Biermer as far back as 1860 Dr Tyson gives an interesting account of the pathology of the affection The interstitial cellular infiltration may be general throughout the kidney or focal, though even when the former prevails the disposition to focal arrangement is still marked, but no satisfactory explanation for this character has been found No distinctive symptoms have been observed in this form of nephritis but it occurs more especially in connexion with scarlet fever and diphtheria

The section on the Dietetic Treatment of Bright's Disease gives a good summary of modern ideas as to the diet to be administered to patients who are the subjects of this affection Dr Tyson's views closely correspond with those of Professor von Noorden The indications both in acute and chronic nephritis are to spare the kidney as far as possible and to prevent the accumulation of toxic substances in the blood A purely milk diet (with the addition of cream) is suited to the acute form but is not so desirable for prolonged use Attention is rightly drawn to the erroneous and ill founded notions which have arisen in some minds with regard to meat food, especially as to the difference between white and red meats , it has been demonstrated that the quantity of proteid in raw white meat is little less than in raw red meat Contrary to the opinion formerly held that no flesh food should be given in nephritis, many authorities now hold that some meat is necessary in cases of contracted kidney in order to maintain a high degree of bodily vigour Dr Tyson insists upon the fallacy of the older doctrine and advises patients with chronic nephritis merely to limit their consumption of all meats rather than of any one kind He also doubts the efficacy of recommending copious quantities of water in chronic renal disease, although this plan is generally adopted and with apparent success

Turning to the portion of the volume dealing with diabetes, we find an excellent *résumé* of the present knowledge concerning the pathology of this disease The various theories elaborated by different observers are duly considered and out of a somewhat chaotic collection of facts Dr Tyson arrives at certain conclusions which he expresses very clearly as follows —It appears possible to make three categories of all cases of glycosuria First, cases of alimentary glycosuria whereof diminished carbohydrate ingestion is the treatment Secondly cases of nervous lesion or diseases in which directly or indirectly through the nervous system the inhibitory centre in the medulla oblongata is deranged and an active hyperæmia of the liver and consequent glycosuria *result These cases* recover if the nervous lesion is curable Thirdly cases in which there is no lesion or disease of the nervous system but in which the symptoms of diabetes are very pronounced These for convenience Dr Tyson denominates ' essential diabetes ' In a certain proportion of these the pancreas is diseased , in others no change in this organ is discoverable In the present state of divided opinion as to the pathology of diabetes, the above is a good classification upon which to found clinical procedures, but further investigations are certainly desirable in order to attempt to solve a very difficult problem The directions for the treatment of diabetes are given in a clear and complete manner , the dietetic and hygienic requirements are fully discussed as is also the treatment by drugs

Taking the work as a whole, we can recommend it as being carefully and accurately written It contains numerous practical suggestions as to the treatment of Bright's disease and diabetes and also gives a good idea as to the most favourably received theories in regard to etiology and pathology.

LIBRARY TABLE.

A Nurse's Handbook of Obstetrics. By JOSEPH BROWN COOKE, M.D. Philadelphia and London: J. B. Lippincott and Co. 1904. Pp. 391. Price 9*s.* net.—This book is primarily intended for the pupils in the New York City Training School for Nurses, with which the author is associated. The work is a good example of its kind and contains just that amount of information which it is necessary for every maternity nurse to know. Some of the author's teaching we are inclined to disagree with but on the whole the book forms a very fair and trustworthy guide for an intelligent nurse. We notice that a correct description of the advantages of the binder is given and Dr. Cooke does not repeat the old fallacy that the binder has any real effect in preserving the patient's figure. The instructions given with regard to the changing of the vulvar pads are good, but we are surprised to find that the position on the back is recommended as the best for passing the catheter. In our experience the lateral position is in every way preferable and enables the catheter to be passed much more easily and readily, especially when the parts are swollen after labour. We are aware that nurses are usually taught to pass this instrument when the patient is lying on her back but a trial of the lateral position will very soon convince anyone that this is the easier and better method. The statement on p. 20 that when eclampsia originates after labour it is of a far more serious character than when it occurs either before or during labour is hardly warranted by the facts. On p. 205 the method of packing the uterus with gauze for post-partum hæmorrhage is given undue prominence. It is a procedure which is practically never necessary if the hot douche is used properly. In Chapter XIX. on the Management of the Puerperium the nurse is instructed to hold the fundus uteri through the abdominal wall for one full hour after the birth of the child, but nowhere in this chapter do we find any mention at all of the expression of the placenta and there is nothing to tell us that the author is assuming that the placenta has already been expressed. If it has not been expressed then the directions as to the arrest of hæmorrhage are misleading and if it has been then there is no necessity to hold the uterus for one whole hour after this has occurred. We are glad to see that the old-fashioned method of hardening the nipples with brandy or some similar lotion is not recommended but the very sound advice is given to soften them before labour with lanoline or some similar substance to prepare them for suckling. The illustrations are satisfactory. There is a very useful glossary and the book is one which we can recommend as suitable to nurses.

Ward, Lock, and Co.'s Illustrated Guide Books. London, 1905. Twenty-sixth edition. Pp. 336. Price 1*s.*—That a book has reached its twenty-sixth edition shows pretty well that it answers the purpose for which it was written, and the guide now before us will certainly be found very useful by those for whom it is mainly written—namely, the countryman and the foreigner. We notice one curious omission in the section entitled "The Railways of London." The metropolitan termini of the various companies are given, Cannon-street being alluded to, but there is no mention of Charing Cross, except incidentally under the heading of Charing Cross Station on the "Underground" which is described as being "close to South Eastern and Chatham terminus of same name."

Medical Philology. Gathered by L. M. GRIFFITHS, M.R.C.S. Eng. Part I., A—El. *Bristol: J. W. Arrowsmith.* 1905. Pp. 100. Price 2*s.* 6*d.*—The matter contained in this book is an enlarged edition of papers which appeared in the *Bristol Medico-Chirurgical Journal* in a department of the journal established under the editorship of the late Mr. Greig Smith. The words dealt with are mostly taken from the "Promptorium Parvulorum" and from the "Catholicon Anglicum," two fifteenth-century English-Latin word-books. Mr. Griffiths has got together a vast amount of interesting information. For instance, many readers of Anstey's delightful "New Bath Guide" must have been puzzled by the following passage in Letter XI.:—

> "See little Bob Jerom, old Chrysostom's son,
> With a chitterlin shirt, and a buckle of stone."

Chitterlings, of course, are "the inwards, or hogs' guts dressed for food which are much shrivelled or curled up, from whence the cambric ornaments worn upon the shirts of most men at this (1750) time are so called, because of their being gathered in folds or plaits" (Dyche and Pardou's Dictionary). We look forward with interest to the remaining parts of Mr. Griffiths's book.

How to Keep "Fit," or the Sailor's Guide to Health in all Parts of the World. By Fleet-Surgeon W. G. K. BARNES, M.D. R.U.I., R.N. Portsmouth: Gale and Polden. Pp. 37. Price 3*d.*—This little book has received warm commendation from Lord Charles Beresford and we quite agree with his opinion. The directions are admirable and are expressed in perfectly plain and simple language. Not only men in the Royal navy or in the army but also civilians will profit largely by reading them. We see that Fleet-Surgeon Barnes recommends (p. 28) oil of pennyroyal to keep away mosquitoes. In our experience the oil of mentha pulegium is of little use, whereas we have found the oil from the pennyroyal of the United States (hedeoma pulegioides) decidedly successful.

Obstetrics for Nurses. By JOSEPH B. DE LEE, M.D. Fully illustrated. London, Philadelphia, and New York: W. B. Saunders and Co. 1904. Pp. 460. Price 12*s.* net.—This book considers two subjects—obstetrics for nurses and obstetric nursing, and the author has combined them so that they may be mutually helpful one to the other. The work is divided into three parts; the first deals with the anatomy and physiology of the reproductive system, the second with nursing during labour and in the puerperium, and the third with the pathology of pregnancy, labour, and the puerperium. We are glad to see that the author recommends during pregnancy the application of cocoa butter or albolene to the nipples instead of the astringent washes or alcohol so commonly employed, for as he points out the nipples should not be hardened but rather kept soft and pliable. The directions for the care of premature infants are particularly good and so is the section on the various methods of artificial feeding. There are an appendix on visiting nursing in obstetric practice and a useful glossary and full index. This is a book which can be recommended to nurses.

A Text-book of Gynecology. Edited by CHARLES A. L. REED, A.M., M.D., Professor of Clinical Gynecology in the Medical Department of the University of Cincinnati. Second edition, revised. London and New York: *D. Appleton* and Co. 1904. Royal 8vo, pp. 900. Price 21*s.* net.—This work has passed through successive printings with such rapidity since its first appearance that no very extensive revision has been necessary. In the present edition, however, some changes have been made and some of the paragraphs, more especially those relating to details of treatment and technique, have been rewritten. The book retains its essential characters quite unaltered and we noticed the first edition at length in the issue of THE LANCET of Nov. 2nd, 1901. There is no change in the number of pages and the list of the contributors remains the same. It is a pity that in producing a so-called second *edition* the editor did not seize the opportunity to carry out a more complete revision. The treatment advocated on page *424* for the removal of polypi from the interior of the uterus by the employment of the old-fashioned wire écraseur would then no doubt have been amended. We cannot imagine any modern surgeon employing such a useless and antiquated method of dealing with these tumours. Further down the page we are told that in the case of large polypi the cervix should be incised and then dilated with the finger or a steel dilator—a very certain way of tearing the tissues with no corresponding advantages. Surely it is time the old fallacy that hæmorrhage takes place from the pedicle of these tumours after their removal, which cannot be quite controlled either by a gauze plug or a hot douche, should no longer find any place in a so-called modern text-book. A number of minor errors, mainly in the spelling of names and in the references, still remain and detract from the value of the work. The volume is, on the whole, one which presents many features of interest and a good deal of originality in its arrangement, but like all works by a number of authors there are a certain amount of overlapping and a great difference in the merits of the various sections.

The Principles and Practice of Asepsis. By A. S. VALLACK, M.B. and Ch.M. Syd., Surgeon to the Berrima District Hospital, New South Wales. London: Baillière, Tindall, and Cox. 1905. Pp. 95. Price 2s. 6d. net.—The aim of the author of this small [illegible] and efficient system [illegible] points which are so[illegible] The first is the importance of conserving tissue resistance; the second is the advisability of avoiding contamination of the hands with microbes of high virulence; and the third is the extreme *difficulty of sterilising organic substances such as* catgut. There is an introduction by Dr. W. J. Smyly in which he states his opinion that "this work is a useful addition to the literature of this most important subject." Dr. Smyly writes that he thinks that "*the most important facts clearly* brought out in this work appear to me to be that it is impossible by any known method to render hands which have been already contaminated with septic matter pure; and that therefore it is *necessary to cover them* with sterilised rubber [illegible] by following the rules laid down he will be able to bring his own operation cases to a successful issue. The author regards rubber gloves as the greatest advance in asepsis since the practice of boiling instruments was introduced. At p. 29 it is stated that a solution of perchloride of mercury in glycerine is inert, yet it is, we believe, used largely as a lubricant. At p. 74 there is a very evident error in the wording of the axiom dealing with the great principle of the treatment of wounds. The axiom as printed is controverted by the corollary. This printer's error should not have escaped the reader of the proof. It sounds almost paradoxical to state that in dressing a septic wound aseptic precautions should be observed, yet this is most necessary, lest a fresh variety of microbe may increase the virulence of the infection. The little book will repay those who read it.

The Sanitary Inspector's Handbook. By ALBERT TAYLOR, Member of the Royal Sanitary Institute. Fourth edition, with illustrations. London: H. K. Lewis. Pp. 455. Price 6s. net.—This work has been thoroughly revised, illustrations added, and the text and index amplified, but the arrangement of the subjects remains as in the last edition. To the alphabetical synopsis of the law [illegible] able to England and Wales and t[illegible] in the second edition the provisions of the Public Health (Scotland) Act, 1897, have been added in a separate column. The by-laws of the London County Council relating to the construction of drains, water-closets, soil-pipes, and to the depositing of the drain plans have also been inserted. Sanitary inspectors and those seeking to qualify for such appointments will find the book a useful guide upon all questions concerned in their official work. The book supplies practical information and it may safely be consulted by those who take an interest in sanitary subjects. We note a few printer's errors but the general get-up of the book—the print, the paper, and the illustrations—is good.

Essays in Puritanism. By ANDREW MACPHAIL. London: T. Fisher Unwin. 1905. Pp. 257. Price 6s.—The essays which make up this book were first read before a company of artists who "had the traditional antipathy of their class towards the spirit of Puritanism." Those who read them are asked to keep this local circumstance in view. The essays are five in number; they treat of the lives and doings of Jonathan Edwards, John Winthrop, Margaret Fuller, Walter Whitman, and John Wesley. The essays are written in an interesting way and contain much that is edifying and instructive; occasionally, though rarely, passages are amusing.

In Loco Parentis: Chapters on Institution Life and Work. By the Rev. MARSHALL GEORGE VINE, B.A., Warden and Resident Chaplain of the Philanthropic Society's Farm School, Redhill, Surrey. With a Preface by JAMES GRANVILLE LEGGE, His Majesty's Chief Inspector of Home [illegible] hools. London: John Murray. 1905. Pp. 83. [illegible] 6d. net.—This book can be commended to the [illegible] all engaged in the bringing up of children. It is one which will charm and cheer parents and guardians and at the same time strengthen the resolve of all those who are doing their best to bring up boys to be good men and good citizens of the empire. The idea of writing these chapters was derived from reading Mr. A. C. Benson's lately published book "The Schoolmaster." It occurred to the author that he might be able to encourage and to strengthen the hands of some of his fellow workers in institution schools if he were to offer some remarks derived from his considerable experience of such work. Although the book deals specially with the boys received into the institutional schools, yet we know of no class of boys or of instructors to which the sound sense contained [illegible] lume does not apply. As the author truly says, "[illegible] to all influence over children is to gain their [illegible] and love, if these be won the moulding of character becomes an easier task." Mr. Vine pleads for a preliminary diagnosis of character, for a consideration of the best place in which to put each boy, and for the thinking out and the adoption from the very first of a deliberate line of training to suit each boy. He also pleads for the special training of masters in the sacredness of their trust, in the study of discipline and how to enforce it, in the importance of conscientiousness in the discharge of duty, and in the domestic aspect and unity of the school household. The words "credo, spero, amo," express the principles which should animate institution work and school life, the chapters of this book inculcate the concrete application of them.

ST. MARY'S HOSPITAL.—At a special meeting of the supporters of this hospital held on May 9th under the presidency of Mr. H. A. Harben, chairman of the board of management, the Mayor of Paddington proposed a motion, which was unanimously adopted, to the effect "That this special meeting of governors and subscribers to St. Mary's Hospital is of opinion that it is of the highest importance to the welfare of the hospital that the £60,000 required (1) for the completion of the [illegible]k of enlargement and improvement which has now [illegible]n in progress for upwards of 12 years, and (2) for releasing the general maintenance fund from debt, be obtained without trenching on the small invested capital of the hospital which represents the accumulated savings of half a century, and that the annual income be increased to meet the enlarged expenditure entailed by the increased size of the hospital."

THE LANCET.

LONDON: SATURDAY, MAY 13, 1905.

International Amenities.

THE visit which is now being paid by British physicians and surgeons to Paris and to some of the French watering-places is an event calculated to afford much more than a merely temporary gratification. It is a step, and an important one, towards strengthening the ties of international friendship between free peoples who are in many respects complementary to each other and who have only been kept apart by artificial influences. The cordial alliance that subsisted between HENRI IV. and ELIZABETH, like that which subsists between the French Republic and ourselves to-day, should be regarded as a true expression of our proper relations with our nearest neighbours; and the traditional enmity between France and the England of GEORGE III. was a mere accident due to the opposition of a land of liberty to the ambition of NAPOLEON. The two countries have long ago returned to a more correct sense of their respective duties and obligations and to a conviction of the services which their union is certain to render to the causes of enlightenment and civilisation, and this conviction has been strengthened and confirmed by the consummate tact of our own gracious sovereign, as well as by the political sagacity of M. DELCASSÉ and of Lord LANSDOWNE. Nothing can be more suitable than that the members of the learned professions should follow the examples which have been set them by the rulers of the two countries and should seek, in the attainment of better knowledge of one another, a sure foundation for mutual respect and goodwill. It is to the Frenchman who does not know England or the English, and to the Englishman who does not know France or the French, that the enemies of both nations address themselves. We fear it is less common to-day than it was a generation or two ago for our medical students to regard a sojourn of some duration in Paris as a step essential to the completeness of their education; and the change is no doubt partly due to the greatly increased facilities for travelling which render it so easy "to run over" for a week. In former times, when a journey was a more serious undertaking than it is at present, those who went at all went to remain for a considerable period and, naturally, sought all available opportunities of studying under the great masters of medicine and of surgery and of making friendships of an enduring character. Of the consequences of those friendships some of us now in the decline of life have been privileged to speak and have met the greatest Frenchmen of their day at the houses of English entertainers. The visit of M. RICORD to London, soon after the termination of the Franco-German war, was an event which will live in many memories and which afforded to many of us an opportunity of hearing his own recollections of English worthies who had been the contemporaries of our grandparents.

In matters of science it is not the least of the many uses of friendship between nations that it facilitates new applications of discoveries in circumstances different from those in which they originated; and that it thus tends directly to increase their fruitfulness. It might be thought that philosophy would rise superior to national antipathies but such a view is not confirmed by experience. PASTEUR, in 1868, received from the University of Bonn an honorary diploma as Doctor of Medicine, in recognition of the fact that "par ses expériences très pénétrantes il avait le plus contribué à la connaissance de l'histoire de la génération des petits organismes et avait fait heureusement avancer la science des fermentations;" but in 1871 he declared the sight of the parchment to be odious to him and returned it to the Dean of the University, with the explanation, "Je me sens offensé de voir mon nom, avec la qualification de *Virum Clarissimum* dont vous le décorez, se trouver placé sous les auspices d'un nom voué désormais à l'exécration de ma patrie, celui de *Rex Gulielmus*." It would hardly have been possible in such circumstances as these for any German savant to have made the applications of PASTEUR'S discoveries which were made soon afterwards by Lord LISTER or to have obtained for them prompt and grateful recognition in his country, and the impediments to the progress of science arising from national antipathies have more than once been strongly displayed. At a great International Medical Congress held in Philadelphia in 1876 it was remarked by many of those present with what remarkable frequency representatives of the southern States were found to take views opposed to those which were put forward by representatives of the north, although the questions at issue were always purely scientific and although eleven years had elapsed since the termination of the Civil War.

The ordinary Englishman on a holiday, be he a physician, surgeon, or member of some other calling, is, as a rule, chiefly desirous to leave his profession behind him, and hence, even if he be in France, is little likely to become conversant with the improvements to which at first sight he might have been expected to attend. The physician or surgeon will be more likely to visit theatres than hospitals or museums and will be more likely to be brought into contact with the members of any other profession than with those of his own. It is therefore an especially valuable characteristic of the visit now in progress that it is definitely medical in its nature and objects and is devised as a means of enabling the profession in Paris to exhibit to their British *confrères* all that is most worthy of their professional notice. The time will be too short, the days will be too crowded, for much to be learnt even by visitors of the most inquiring minds and of the most retentive memories, but everyone will see something fresh and everyone will accomplish some sort of natural selection among the novelties that chiefly appeal to him. Above all, and in contradistinction to some of the instances already mentioned, the visitors will bring with them friendly eyes and a disposition to see the best and most useful aspects of all that is submitted to them. It would be an excellent thing if the organisation by which the present visit and the recent visit to London o

French physicians and surgeons have been planned and rendered effective could remain in existence as a more or less permanent institution, so arranged as to afford to practitioners on either side of the Channel information concerning whatever might be best worth seeing on the other, and with facilities for affording introductions which might help visitors on their way. Every step taken in this direction would be contributory to the intellectual fusion of the two nations and to the utilisation in each country of the somewhat differing powers and capacities of the other. We should like to see the revival of the old custom to which we have referred and the frequent sojourn in France of English medical students as an important part of their preparation for the serious work of their calling, more especially because such a procedure would convince both Frenchmen and Englishmen that a competent mastery of the tongue of the other country is a matter not wholly beyond the reach of ordinary care and diligence, and that it is one calculated to bring with it a rich reward. The suggestion brings to mind an old epigram which, if not strictly medical, may at least be said to have a medical aspect:—

"The French have taste in all they do,
[illegible]

Accidents Connected with Motor-Cars.

AN answer recently given to a Member of Parliament by the Home Secretary shows that during last year the police reported 21,771 accidents as having been caused by horse-drawn vehicles and 2079 as due to motor-cars. These large figures, from which accidents connected with tramcars have been omitted, no doubt include many very trifling cases of collision to which the attention of the nearest policeman has been called and which have accordingly found their way into his note-book, but the proportion of those due to motor-cars is considerable. Still more is it noticeable when we turn to the number of fatal accidents, of which 120 were due to horse drawn vehicles and 19 to motor-cars, including motor bicycles. If, moreover, the prominence given to motor accidents recently in the newspapers and their apparent increase in the streets of London afford any guide, we may hazard the opinion that for the current year the number of accidents and fatalities will be greater still. The matter is one of considerable interest to the public and particularly to the medical profession who can appreciate the nature of the injuries likely to be caused by motor-cars of any kind as compared with those inflicted by horsed vehicles of the lighter classes. Medical men also are not only users of motor-cars but of all members of the community have most frequently a good reason for wishing to be driven rapidly, while desiring to be so conveyed with the least possible danger to their neighbours. There are with motor-cars many dangers not connected with the desire for extreme speed, referred to in a recent annotation in THE LANCET under the heading "Motor Maniacs,"[1] but which may arise when the car is travelling well within the 20 miles per hour allowed by statute. These dangers may even in some measure be due to the ease with which the mechanical vehicle can be directed and handled and to the undue sense of confidence which it thus inspires.

Without analysing too minutely the psychology of the chauffeur and of the coachman we may suggest that the latter has more to compel him to caution than the former in the vulnerability or possible nervousness of his horse, and that when, for example, he approaches a blind corner he thinks as much of what may run into him as of what he will have to avoid running into. The instinct of the chauffeur crossing a main thoroughfare seems to urge him to use his speed in order to dart across it rather than to give way to the traffic occupying it. A chauffeur was recently fined £10 at the Marylebone police-court for acting in this manner, thereby endangering the safety of a hansom cab and its occupants. If, on the other hand, the driver of a motor-car desires to turn into the road which he has approached and to proceed along it—in other words, to go round a corner—he forgets that the ease (and safety to himself) with which he can do so may be a source of danger to foot passengers not aware of his intention. The coachman who advances towards a corner at a fast trot has to pull his horses together and to take them round it at a greatly reduced pace, and apart from such signal as he may give with his whip it is not difficult for those near to see what he is about to do. The motor-car, on the other hand, can spin round the angle without lessening what may seem to its driver a moderate speed but at a rate extremely startling and perhaps dangerous to the unwarned pedestrian who may have left the pavement The hired motor-car driver, in short, has not got to consider his own safety and has not learnt to think of the safety of others, his apprenticeship, if he undergoes any, does not imbue him with the traditional courtesy of the road and he seems to be slow in acquiring it. A recent accident, reported in the newspapers owing to the resulting inquest, although death was not entirely due to the injuries inflicted, happened thus. A motor-car driver closely following an omnibus simultaneously quickened his speed and turned outwards in order to pass it, knocking down a foot-passenger who had safely crossed in front of the omnibus. There was another vehicle on the off-side of the motorist, so that he could not avoid the man, and as there was no time to pull up he ran into him. Three points may be referred to here as probably contributing to the accident, all of which directly affect the automobile. The driver, as a rule, is seated much lower than is the coachman and often assumes an attitude which suggests the easy chair rather than the alertness appropriate to the box-seat; consequently he is more likely to have his view of the road ahead of him shut out. The coachman driving behind another vehicle has his horse between him and it, and consequently can see farther to the right or to the left than the motorist, who can, and often does, follow so closely that the end of his car almost touches the obstruction in front of him. Here, again, is a cause which prevents him from seeing what is beyond until he has actually turned outwards in order to pass. When he desires to pass, moreover, the motor car driver can increase his speed with a rapidity impossible in the case of the horse, so that he is liable to dash upon whatever lies in his way with a suddenness unknown to the driver of horses. The essential point to remember where speed is concerned is that there may be plenty of time for the driver or for the person endangered to do what is required, but there may not be time for either of them to make up his mind on the subject. When we consider that a car travelling at the rate of 20 miles an hour traverses a fraction less than ten yards in a second we can easily understand the apparent helplessness of persons injured who, according to some of the opinions expressed after an accident, might have got out of the way.

---

[1] THE LANCET, April 22nd, p. 1083.

The dangers occasioned by the tendency of the motor vehicle with indiarubber tyres to skid upon greasy roads appear to be regarded frequently by those driving as more or less inevitable accidents but are, as a rule, due to want of foresight and to the consequent sudden necessity of rapidly checking the speed. It is obvious that if a motor-car having only space in which to travel straight forward suddenly spins round and commences to proceed broadside on much damage may be done to vehicles, horses, and persons in its vicinity. If these occurrences are to be regarded as inevitable in muddy weather motorists will some day have the proposition submitted to them that vehicles which at certain times are inevitably dangerous must at those times be kept at home. An accident of this class was reported recently in the newspapers in which the vehicle which skidded was one of the large motor omnibuses of which a few are plying for hire and the vehicle with which it collided was a hansom cab. In another instance an electric motor-car is stated to have injured seriously the horses, van, and driver of a furniture remover. In considering the question of motor-car accidents the serious nature of the damage to person and property which such heavy vehicles must necessarily cause has to be considered, and in view of the threatened increase in the number of these vehicles many will feel doubts whether a mistake has not been made in placing the limits of weight permitted to a "light locomotive" so high. We have referred to omnibuses, some of which are of a size hitherto associated with tramcars rather than with ordinary road vehicles. A few of these are to be seen here and there threading their way through the more slowly moving horse traffic without much apparent difficulty. It will be a very different matter when a large proportion of the vehicles of the great omnibus companies and of rival organisations are of this type and are competing with one another for passengers. This and the probable increase of motor traffic of all kinds will render our streets extremely dangerous unless care is enforced upon drivers far more strictly than it has been up to the present and by different means.

◆

Identification by Finger Prints.

THE question of the value of the impressions of the ridges on the palmar surface of the hands, especially those on the terminal divisions of the digits, for the purposes of establishing identity has of late years come prominently to the front, and events at a recent trial for murder have brought the whole matter into particular prominence just now. It has long been known that the patterns formed by the palmar ridges show a considerable variety both in their general arrangement and in detail, and when a clear impression of these is placed on paper or other suitable smooth surface and compared with another clear impression, taken previously or subsequently, of the same digit it is not usually a matter of much difficulty to recognise the similarity and minute correspondence that exist between them. Again, if clear impressions have been taken of different fingers their diversity is readily apparent on comparison, especially if the patterns be not very closely allied, but in other instances it may be necessary with the aid of a magnifying glass to study more or less carefully and in detail the various parts of the print before being able to determine their dissimilarity. The task of determining the identity or non-identity of a set of finger prints is rendered more easy by the fact that if the patterns of any two corresponding digits be not very apparent there are nine other pairs which are available for comparison, the agreement or disagreement of each successive pair of which confirms the identity or non-identity of the prints compared in an ever increasing ratio till the certainty of the result may be absolutely relied upon. On the average each digit gives about 35 points of comparison, so that the mass of evidence afforded by the ten digits is very great, and the factor of personal error is reduced to a minimum, as the digit itself is made to record on the paper the data which it contains. In classifying records of finger prints their small size necessitates in many cases the use of a magnifying glass for their examination, which is decidedly a drawback, but the expert very quickly gets accustomed to the work and is able to do it accurately and rapidly.

Prints of all the fingers of prisoners who have been convicted in this country and sentenced to imprisonment for certain crimes are taken previously to their liberation at the expiration of their sentences and are sent to the Metropolitan Police Office for record. If in a set of prints of any prisoner some are faulty they can be retaken before his discharge from prison; a good set of prints can therefore be secured for classifying at headquarters together with the particulars as to every such prisoner's conviction. In the prisons certain officers are specially selected for the purpose of taking finger impressions and with the practice which they now have they are able to produce good work. An unconvicted prisoner may, on a regular application made in writing to a magistrate being granted, be required to submit to the impressions of his fingers being taken by a prison officer with the view to ascertain whether he has been previously convicted of any offence. Here, again, the prints are taken by practised officers and sought for and compared at the Metropolitan Police Office by equally practised persons. When a set of finger impressions previously taken in a prison is found by the officers of police in the central office to agree with another such set sent from a prison, in most cases it may be safely assumed that the identification is correct, notwithstanding that the two sets of impressions have only passed through the hands of men with no knowledge of the anatomy of the fingers and with only the average education of policemen. But in the interval which has elapsed between the taking of the two sets of impressions cuts and injuries to one or more of the fingers may have occurred whereby the data for comparison may have been diminished. It is therefore, perhaps, somewhat an open question whether, in the interests of the public, in cases where previous conviction is to be proved against a prisoner, the data should not first be submitted for confirmation to some independent authority possessed of anatomical and physiological knowledge. The state of the law on the subject of proving previous convictions against a prisoner is so highly unsatisfactory and dangerous that to get the unchecked testimony as to identity derived from the impressions of several fingers as a backing to mere memory is a decided advance, but too much stress must not be laid upon the backing. Recognition by memory of the prisoner by someone present at his previous trial and conviction is the usual means employed at the present time of proving previous convictions in court. Some police officers, no doubt, have good memories for faces, but the reliance that is to be placed upon such recognition after perhaps an interval of several years is obviously most uncertain. Identification by finger prints is here very valuable but the identification should be made by properly expert persons.

Turning now to the employment in other circumstances of finger impressions for purposes of identification—namely, when a digital impression is discovered on some substance at the scene of a crime and comparison of that impression is made with the prints of the fingers of a person arrested on suspicion of being the perpetrator of the crime—a very different condition of affairs obtains. The prints of the person under arrest are made on paper from the fingers properly inked—that is to say, with the tops of the ridges covered with ink of an exact consistency and the furrows between them free from ink. But the impression of the digit found at the scene of the crime has been the result of the contact of a finger moistened by the natural excretions of the skin or in some cases it may be by blood; dust or dirt of one kind or another will be on the surface of the finger; the surface on which the impression is found will vary and may not be of a nature suitable to record a satisfactory impression—all these things, which might be multiplied, make a fair comparison between such an impression and what may be called an official impression difficult, while the pressure with which the impression may have been made introduces another complexity to the already unequal conditions. In fact, the widest possible range of variation may occur in casual finger imprints from a good clear impression of the whole, or part of it, as is sometimes found on glass or porcelain, to a blurred or imperfect print upon a poor medium out of which it is well nigh impossible to obtain any information. In such cases great skill and caution are necessary to read the imprints and the ultimate certainty on which any statement as to identity can be based is enormously reduced, particularly if an impression of one finger only, presenting a few points of similarity, is available. In such a case the importance to be attached to the absence of clear points in the accidental impression corresponding to those in a carefully taken impression, even although the general pattern of the two prints corresponds, becomes very real, and for the due consideration of the matter it seems to us that the person called upon to examine and to advise as to identity or non-identity should possess thorough and practical knowledge as well as trained mental powers of discrimination. To intrust the duty to partially skilled persons is in the highest degree dangerous from a public point of view.

Annotations.

"Ne quid nimis."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

Mr. George Herring has again offered to add one-fourth to any amount collected in places of worship on Hospital Sunday, his liability not to exceed £25,000. In a letter addressed to the secretary of the Fund in which he makes this offer he adds: "I hope the calls on the charitable for building purposes will not decrease the collections for the *maintenance* of the hospitals, as I think that should be the primary object." As was pointed out at a meeting of the council of the Fund held at the Mansion House, under the presidency of the Lord Mayor, on May 9th, it rests wholly with the congregations attending the various places of worship in the metropolis whether the full amount of £25,000 can be secured. The motion that Mr. Herring's munificent offer should be accepted was received with unanimous acclamation by the council and we know that he has the gratitude of the whole of the community, the individual members of which will, we trust, this year show that gratitude in a practical manner and enable the generous giver to contribute the £25,000 which he offers towards the maintenance of the sick and suffering poor of London. It would be most regrettable if the appeals which are now being made on behalf of the building funds of various London hospitals should influence detrimentally the subscriptions to the Metropolitan Hospital Sunday Fund. That great efforts will be made this year to reach a record collection we have every reason to hope, especially as, on the suggestion of Mr. Deputy Wallace, the representative of the Corporation of London, the Lord Mayor has promised to send a letter to the various mayors of the metropolitan boroughs asking them to call attention to the Fund and personally to address letters to the clergy on the matter. Among the members of the council present at this meeting were, in addition to the Lord Mayor, Sir Sydney Waterlow, who has been chairman of the Distribution Committee for the past 34 years, the Ven. Archdeacon Sinclair, the Chief Rabbi, Sir John Bell, Mr. Felix Schuster, Mr. Wakley, Dr. J. G. Glover, Mr. Thomas Bryant, and Mr. Alfred Willett.

VINCENT'S ANGINA.

IN THE LANCET of July 16th, 1904, p. 135, we published a paper from the pen of Dr. H. W. Bruce on Vincent's Angina. This form of pseudo-diphtheria, which was first described by Vincent in 1898, is important because it is a disease which is very likely to be mistaken for diphtheria and in that case, as Dr. Bruce well said, "the dread which that disease still inspires and all the inconveniences of isolation will be inflicted unnecessarily upon the patient. Treatment will be wrongly directed and prognosis will be faulty." At p. 1260 of our present issue will be found an article upon Vincent's angina from the pen of Professor Vincent himself. Professor Vincent was anxious, seeing that we had already published one paper upon the subject, to lay his own views in his own words before his professional brethren upon a disease which is but little known. As during this week British medical men are enjoying the hospitality of their French *confrères* we have considered it a fitting opportunity for the publication of Professor Vincent's paper and we have thought it appropriate to give the paper in the language of its author rather than to translate it. Dr. Bruce's admirable paper was illustrated by an account of ten cases of the disease following a description of the clinical characters and bacteriology of the complaint. Professor Vincent, while giving no account of any particular cases, goes very fully into the symptomatology and diagnosis of the disease and mentions a point not considered by Dr. Bruce—namely, the treatment. This is simple and consists in the local application of iodine. To use Professor Vincent's words, this serves as a touchstone to differentiate between Vincent's angina and ulcerative syphilitic disease of the throat. We may hope that the publication of these two papers will draw the attention of our readers to a disease which, though not uncommon, is apparently frequently unrecognised.

UNIVERSITY COLLEGE, LONDON.

A COURSE of ten lectures will be given by Dr. W. Page May, Fellow of the College, on the Structure and Functions of the Central Nervous System, on Wednesdays, at 5 P.M. The subject of the first lecture, given on May 10th, was Methods of Investigation, Ganglion Cell and Nerve Fibre, the Nerve Arc, Degeneration, and Regeneration. The second lecture will describe the Spinal Cord, its Nuclei, its Conducting Paths, and questions of Localisation. Lectures 3 and 4 will deal with the Structure and Function of the Centres and Paths in the Brain Stem (Medulla, Pons, and Mid-brain). In Lecture 5 the Cerebellum, its Cortex, the Peduncles and their Functions will be described. The subject of Lecture 6 will be the Basal Ganglia, with Special Reference to the Optic Thalamus and Corpus Striatum. Lectures 7 and 8 will be devoted to the Centres and Paths of Vision, Taste, Hearing, and Smell. The subjects of Lectures 9 and 10 will be the Cerebral Hemispheres (Motor, Sensory, and Psychic Areas) and the Main Afferent and Efferent Paths of the Central Nervous System. These lectures are open to internal students of the University of London without fee as well as to medical practitioners on presentation of their cards.

THE STRUCTURE OF NERVES AND ITS APPLICATION TO NERVE ANASTOMOSIS.

IN the *Archives Générales de Médecine* of March 14th M. L. Bruandet and M. Humbert have published an important paper on the Structure of Nerves and its Application to the Operation of Nerve Anastomosis. They find that the fibres of a branch of a nerve do not lie adjacent to one another in the trunk but scattered among other fibres. They become grouped together only on emergence from the trunk or in the last few millimetres of their course in the trunk. This view might be confirmed by studying the degeneration in the branches of a nerve which follows hemisection of the trunk. Degeneration ought to be found in about half of the fibres of each branch. M. Bruandet and M. Humbert have not performed this delicate anatomical study but they have made the corresponding physiological experiment. They performed hemisection of the sciatic nerve of a dog and found that the same motor effects were produced when the nerve was stimulated above the point of section as when stimulated below it. Moreover, the animal was able to perform all the movements of the limb in locomotion. Cases of accidental incomplete wounds of nerves point to the same conclusion: movements are not seriously affected. Thus the nervous supply of the muscles seems to be normally in excess of what is necessary and therefore can be reduced considerably without much loss of movement. A similar phenomenon is observed in the vascular system. A large vessel may be suddenly occluded and yet a blood supply reduced by one-half, furnished by the collateral circulation, is sufficient for the tissues. A parallel may also be found in the vegetable kingdom: when half of the trunk of a tree is destroyed by accident the branches continue to live. These facts are not merely of theoretical interest but have an important bearing on the recent operation of nerve anastomosis. In cases of facial paralysis anastomosis of the facial nerve with the divided glossopharyngeal, hypoglossal, or spinal accessory nerve has been performed. But the gain in motion of the facial muscles has been accompanied by loss in the muscles supplied by the nerve used for the anastomosis. Section of the spinal accessory nerve for purposes of anastomosis is followed by paralysis of the trapezius muscle. Hemisection of the nerve is quite sufficient for innervating the facial muscles and is not followed by paralysis of the trapezius. In using nerves more important than the spinal accessory the desire to preserve their function has led to unsuccessful operations. In cases of destruction of the ulnar nerve the lower end has been anastomosed to the median but in order to preserve the function of the latter a "buttonhole" has been made in it into which the end of the ulnar nerve has been implanted. But the operation of nerve suture shows that axis cylinders should be opposed to axis cylinders. To implant the ulnar nerve in the connective tissue of the median nerve is useless. The operation which should be performed, according to M. Bruandet and M. Humbert, is to separate some of the fibres of the median nerve and to unite them to the ulnar, thus preserving the function of the former and restoring that of the latter. The most important function of the hand—prehension—will thus be restored without even the necessity of re-education of the nerve centres, for in this act all the muscles supplied by the median and the ulnar nerves take part. Possibly the action will not be as energetic as formerly but it will be sufficient for ordinary purposes.

AMERICAN QUACK NOSTRUMS.

IN view of the great number of American quack nostrums that are widely sold in this country chiefly by the aid of advertisements in magazines and newspapers it is of interest to read in the *Pharmaceutical Journal*, vol. lxxiv., p. 223, the results of the analysis of such preparations by Mr. Albert E. Leach, Government analyst of Massachusetts. Of "intemperance cures" there are many. In one case a five-dollar package consisted of two bottles of liquid, yielding respectively 41·1 and 28·2 per cent. of alcohol by volume, together with a small bottle of pills containing nux vomica and coated with a very thin layer of gold foil. In another case 12 powders in a box and sold for $1 were found to contain ammonium chloride and milk sugar but were free from gold and alkaloids which were stated to be present. Many "tonics" and "bitters" are sold in the United States for a similar purpose bearing various attractive recommendations, a few of which are here quoted: "purely vegetable, recommended for inebriates," this liquor contained no less than 41·6 per cent. of alcohol; "entirely free from alcoholic stimulant," yielded 25·6 per cent. of alcohol; "sulphur bitters, contains no alcohol," this preparation actually contained 29·5 per cent. but was free from sulphur; "a non-intoxicating stimulant; whisky without its sting," gave 28·2 per cent. of alcohol; and "liquid beef tonic, recommended for treatment of alcoholic habit," contained 26·5 per cent. of alcohol. Next to this type of fraud comes the class of diabetic flours or wheaten glutens. Of 11 samples examined starch was present in all, the lowest yield being 10 per cent., two others under 20 per cent., two between 50 and 60 per cent., and six between 60 and 70 per cent. One sample containing

59 per cent. of starch was described by the proprietor as "protein in its purest form" The price for these flours varied from 11 to 50 cents per pound Taking cigarettes next, the ——— brand of Medicated Cinnamon Cigarettes, purporting to contain no tobacco, were actually found to contain a large proportion, together with cassia and other aromatic herbs The Massachusetts Department of Agriculture takes quite a fatherly interest in the consumers of proprietary medicines, whether intended for inward or outward application The report contains a list of hair restorers, some of them well known in this country, giving the amount of lead present In the 12 articles analysed the percentage varied from 0 3 to 2 32 Nine toilet preparations were found to contain mercuric chloride or some other poisonous salt of mercury in proportions varying from 1 to 15 grains per ounce In one case a six ounce bottle contained no less than 47 grains of corrosive sublimate Some of these preparations have already found a ready market in this country and doubtless others will follow in due course The advertising managers of many of our most widely circulated newspapers and magazines will accord them a cordial reception, with the result that the public, with simple faith in what they read, will buy them as eagerly as they have done in the past It is surely time that some official control was exercised over this growing evil. Cases have been known of anxious wives denying themselves everything but the bare necessities of life in order to save the necessary shillings, and even pounds, in order to purchase an elixir which should cure their husbands of a craving for alcohol These frauds have been exposed again and again but still the Government, by insisting on the use of a revenue stamp, appears to give these nostrums an official value in the eyes of a certain section of the public In France and Germany a rigid control is exercised over the import and the sale of proprietary medicines and in some of the States of North America the departments of agriculture in an official publication name the preparations which have been analysed and found to be fraudulent Fraud takes many forms but by the law of this country it is not fraudulent to sell a worthless preparation for an exorbitant price or to claim for it healing or dietetic properties which it does not possess There is a punishment for the convicted thief and the forger but for the individual who charges an extortionate price for his worthless or almost worthless nostrum and holds out false hopes of its healing properties *we have only a Government department which* steps in and says You shall affix a 1½*d* stamp on every package of the value of 1*s* and if the value of the article is 2*s* 6*d* a 3*d* stamp must be used The subject is a difficult one to deal with but none the less it requires prompt and *drastic treatment No reform would be complete without* prohibiting the sale of nostrums proved to be worthless or dangerous

ABNORMALITIES OF THE GALL-BLADDER AND THE APPENDIX VERMIFORMIS

THE two instances of abnormality occurring in the practice of Dr W K Bouton of Melbourne and communicated to us (*vide* p 1265) by Dr Ferguson Lemon are of more than passing interest In the first case the gall bladder, although in its normal position, was so embedded in the substance of the right lobe of the liver as to simulate a hydatid cyst We infer from the description that liver substance completely ensheathed the organ, if this were so the condition is quite new to us In our issue of Dec. 3rd, 1904, p 1584, we published an annotation on abnormalities of the gall bladder but knew of no instance of the condition now described It is a matter of common knowledge that a bridge of liver tissue may be found arching across the umbilical fissure and concealing the round ligament A similar bridge occasionally conceals the vena cava inferior It is possible that a band of liver substance extending across the fossa for the gall bladder might cause the appearance noted by our correspondent In the second case the greater part of the vermiform appendix was adherent to the front of the ascending colon and near its tip had perforated into the peritoneal cavity The proximal part of the appendix lay free and it was by tracing this upwards that the nature of the perforation was discovered The consensus of opinion is that when an appendix is adherent and so extraperitoneal the adhesion is the result of inflammation at some earlier period and this appears to be a possible explanation of the condition of affairs described by Dr. Lemon In some cases it is conceivable that during the descent of the cæcum and ascending colon with its mesocolon the appendix lags behind under cover of the latter and may be permanently retained in this position when the developmental adhesion of the mesocolon to the lumbar walls takes place

VITAL STATISTICS IN EGYPT.

IN his annual report on the condition of Egypt for 1904 Lord Cromer says that the want of full and trustworthy statistics in Egypt has for a long time past been felt both in commercial and official circles With a view to remedy this serious defect M Randone, an official of the Custom House department who had shown special aptitude in the preparation of trade statistics, was therefore deputed by the Egyptian Government to visit Germany and Italy in the course of last summer in order to study the systems in force in those countries In a very interesting report which he subsequently submitted M Randone remarks "The work will be easy so long as one has to occupy oneself with commercial matters and the statistics which concern the postal and telegraph services, the railways, navigation, &c, but as soon as one approaches the more important questions of internal economy, such as the registration of births, deaths, marriages, and divorces, the causes of mortality, the professions, cattle, cultivation, and everything that concerns agriculture, that great source of the wealth of the country, one will necessarily encounter numerous difficulties which it will only be possible to remedy gradually." The attempt, however, is to be made and a sum of £E 5000 has been provided in the estimates for the current year with the object of taking some preliminary steps towards the establishment of a statistical service The introduction of vital statistics into modern Egypt dates from the time of Clot Bey who entered the service of Mahomed Ali in 1825 Writing to the Minister of Agriculture and Commerce at Paris on August 22nd, 1851, Dr Clot's successor, Dr Burguières, was able to say 'I can affirm that at present no decease of a suspicious nature can escape the watchfulness of the sanitary authorities The exact number of deaths being known day by day, not only in the towns but even in the smallest villages of Egypt, the slightest increase of mortality must awaken the vigilance of the officials who at once cause an investigation to be made" The exactitude of this statement may, perhaps, be questioned but, be this as it may, there can be no doubt that when the English took charge of Egypt in 1882 the registration of births and deaths was not only worthless from a statistical point of view but also a fruitful source of illicit gain to the universally corrupt sanitary officials. A new system of registration, the work of Franz Engel Bey, was introduced in June, 1885, when registers for births and deaths, drawn up in French and Arabic, were distributed to the larger towns in Lower Egypt In the following year the system was extended to the towns in Upper Egypt and by the commencement of 1887 every village in the country possessing 300 inhabitants and upwards was supplied In this way a beginning was made but the results were necessarily more or less imperfect owing to lack of funds for the remuneration of an efficient staff of registrars. It is to be hoped that now at last the sanitary department may be given the power to carry out efficiently the important duty which it has so long and so creditably tried to accomplish with utterly insufficient means.

PULMONARY FISTULA.

PULMONARY fistula (a communication between the lung and the surface of the body) is seldom observed though it has formed the subject of a number of monographs. At the meeting of the Société Médicale des Hôpitaux of Paris on March 9th M. C. Achard and M. Louis Ramond communicated an important paper on this subject. The causes of pulmonary fistula are various. Previous adhesion of the two layers of the pleuræ to one another being a necessary condition for their production they are rarely traumatic—due to a penetrating wound of the chest. For the same reason they always occur in the course of chronic diseases. They generally originate from an infectious focus which begins outside the lung or in the lung itself; more rarely there are two foci which are first independent and then become fused. The extra-pulmonary foci occur in the skin, in the subcutaneous tissue, in the bones of the thorax, or in the cervical glands. Most often the cause is a tuberculous lesion of the soft parts or of the bones; sometimes it is actinomycosis or cancer of the breast. Pulmonary foci are much the more frequent. They almost always are due to chronic tuberculosis. Rarely they are due to abscess, actinomycosis, gangrene of the lung, bronchiectasis, or empyema. The pulmonary focus ruptures both into a bronchus and into the skin. The following case was related. A man, aged 49 years, was admitted into hospital on August 26th, 1904. In 1870 he was wounded in the battle of Gravelotte by a bullet which passed through his chest. The wounds were a long time in healing and he was in hospital for two years. In the spring of 1900 he had hæmoptysis and again in the summer of 1902. Since the first of these periods he suffered from cough. On examination large cicatrices were seen on his chest. That of the orifice of entry of the bullet was situated four fingers' breadth below, and a little outside, the left nipple, below the sixth rib. That of the orifice of exit was a little below, and outside, the inferior angle of the left scapula. At the left apex in front there were dulness and subcrepitant râles; behind there were dulness in the whole extent of the lung and cavernous breathing and gurgling in the lower two-thirds. On the right side the apex was dull in front and subcrepitant râles were heard over the scapula. There was abundant purulent expectoration. The evening temperature was 101° F. Some days after admission the patient complained of acute pain in the left shoulder. On August 31st a reddish fluctuating swelling was found in the position of the dorsal cicatrix. On Sept. 1st it broke spontaneously and a thick yellowish liquid resembling tuberculous pus flowed out. On the following days the discharge increased and at the same time the expectoration diminished. In the discharge white blood corpuscles and tubercle bacilli were found. The opening enlarged and became crateriform and its borders ulcerated. When the patient coughed air escaped and projected drops of pus. This "fistulous cough" was accompanied by a sound resembling that of the discharge of gas from the anus. On auscultation a loud souffle was heard at the left base with a timbre more tubular than amphoric, no doubt due to induration of the lung around the bronchi and cavities by which air passed into the fistula. The patient left hospital on his own initiative on Oct. 10th. He returned on the 24th much emaciated. The fistula continued to discharge pus on coughing or on deep inspiration. On Dec. 13th hæmorrhage suddenly occurred from the mouth, the nose, and the fistula and death took place in a few minutes. The necropsy showed on the left side of the chest a thick whitish deposit which extended from the clavicle to the diaphragm and covered the lung and pericardium. It was firmly adherent to the organs and had to be dissected from the internal surface of the ribs in order to remove the lung. The deposit formed a dense fibrous coat one and a half centimetres thick over the lung and sent fibrous bands into the latter. The larger bronchi were dilated. Only islets of lung tissue were recognisable. At the apex were irregular cavities which communicated with one another and with a huge cavity in the thickened pleura. At the lower part of the latter cavity was the internal orifice of the fistula. Below it was a thick fibrous mass which extended to the diaphragm. The fistulous track was very irregular and complicated. All the cavities, pleural and pulmonary, and the fistula were filled with blood clot. The right lung showed ordinary tuberculous lesions. M. Achard and M. Ramond think that the wound of the lung, which took such a long time to heal, gave rise to sclerosis and pleural adhesions, impairing the mobility of the left lung and rendering its vulnerability to tuberculosis much greater than that of the right lung. Just as an abscess travels along fibrous aponeuroses, so, they think, the tuberculosis extended along the cicatricial bands, which, so to speak, conducted it to the skin. Hence also is explained the exception in this case to the rule that pulmonary fistulæ secondary to tuberculosis are situated at the apex of the lung.

THE ILKLEY CORONATION COTTAGE HOSPITAL

ILKLEY is a small town with a population of some 6000 in the West Riding of Yorkshire and it decided to erect a cottage hospital as a memorial of the coronation of their Majesties the King and Queen. The medical profession of the neighbourhood warmly supported the scheme, a sum of £2500 was subscribed, a building to accommodate nine patients and the necessary nursing staff was planned and erected, and on April 15th the hospital was formally opened by Professor John Chiene of the University of Edinburgh. The proceedings commenced with a luncheon given by Dr. T. Johnstone. At the opening ceremony itself Mr. B. Nussey, the chairman of the hospital committee, in his speech requesting Professor Chiene to declare the building open, referred to all those who had helped them. In mentioning the Ilkley District Nursing Association, the work of which would now be carried on in connexion with the new hospital, Mr. Nussey said that he must specially commemorate the late Miss Maude who had taken such interest in district nursing and who had bequeathed £500 to the association. He concluded by welcoming Professor Chiene and presented him with a key in memory of the occasion. Professor Chiene in the course of his address drew attention to the fact that cottage hospitals practically began to be built in 1864, a date which coincided with the great movement in surgery which is for ever connected with the name of Lister. He was glad to see that the hospital was to be open for all practitioners in Ilkley to come and to attend their patients. He went on to advise that in cases of accident there should be one medical man appointed to attend to all such for a certain period and that medical man should have an understudy. At the end of the period the chief should become the understudy and the understudy the chief, so would they all learn the value of service. Professor Chiene concluded by referring to the question of the difference in economy of management between Scottish and English hospitals. We are glad to join with Professor Chiene in congratulating Ilkley on the successful realisation of its scheme. A cottage hospital if worked on a sound footing such as has been laid down for the working of that at Ilkley is of inestimable value and we have no doubt that the Ilkley Coronation Cottage Hospital will be a worthy memorial of the event which all concerned have worked so loyally to commemorate.

THE AMOUNTS OF NEON, HELION, AND HYDROGEN IN THE AIR.

SOME time ago we predicted that the ingenious method discovered by Sir James Dewar of using cooled cocoanut charcoal as an absorbent for gases would give considerable assistance to the experimental study of the rare gases of the atmosphere. Sir William Ramsay has not been slow to avail himself at all events of the advantages and convenience of this method. By exposing relatively large quantities of air to charcoal at – 100° C. considerable absorption or condensation took place and the helion and neon were concentrated inasmuch as at that temperature neither element is absorbed in an appreciable quantity. In this way it was possible to deal with 18 litres of air. The quantities found were as follows: one volume of neon in 80,790 volumes of air and one volume of helion in 245,300 volumes of air. These figures proved to be somewhat near a guess made by the same investigator and his colleague, Dr. Morris Travers, in connexion with the investigation in another direction. Incidentally Sir William Ramsay concludes that the amount of free hydrogen in the air must be less than $\frac{1}{50}$th of the volume of combined neon and helion, as the residue of neon and helion must have contained all the free hydrogen in the volume of air used for the experiment. It is hardly possible in the face of these results to attach any significance to the presence in the air of such minute quantities of the gases described, but, of course, it is conceivable that in the neighbourhood of thermal waters a greater proportion would be found.

THE PROPHYLACTIC INJECTION OF DIPHTHERIA ANTITOXIN.

THE experience in Germany of prophylactic injections of diphtheria antitoxin as recorded in two recent papers is so satisfactory as to merit notice. Dr. J. Ibraham of Heidelberg relates his results at the University Children's Clinique of that town in the *Deutsche Medicinische Wochenschrift*, No. 11, 1905, while Professor Wesener of Aix-la-Chapelle, in the *Munchener Medicinische Wochenschrift*, No. 12, 1905, states that for the last 18 months he has administered prophylactic injections of antitoxin in nearly all cases of children exposed to possible infection coming under his observation at the Mariahilf Hospital, and amongst others to the relatives of children taken to the hospital on account of diphtheria. The results obtained by both observers are in almost complete accord. Dr. Ibraham only found one case which developed the disease in spite of the injection and in this one there was at the same time infection by measles and whooping-cough. He comes to the conclusion that all the members of a family in which a case of diphtheria occurs, especially children under ten years of age, should receive prophylactic doses of antitoxin. He recommends that at least from 250 to 300 units of antitoxin should be injected in the case of healthy children, but if the child is suffering from measles, scarlet fever, or whooping-cough the dose should be increased to 500 units. No reduction of dose is necessary for sucklings or young infants. The protection conferred by such doses lasts about three weeks. Professor Wesener regards the method as one offering a valuable but not absolute protection, lasting from three to four weeks, and therefore of sufficient length to adopt ordinary prophylactic measures against spread and to disinfect infected buildings. Even when diphtheria occurs in spite of the injection of prophylactic doses, whether owing to subsequent infection or to infection before the injection, the course of the case is usually mild. He thinks that in most cases 200 units are sufficient to give protection but recommends the employment of from 300 to 400 units if possible.

THE LONDON SCHOOL OF TROPICAL MEDICINE.

THE banquet held on Wednesday evening with the object of relieving the London School of Tropical Medicine from a heavy burden of debt has drawn public attention, mainly through Mr. Chamberlain's forceful speech, to the affairs and performances of a most deserving scientific institution. Although it has been but a few years in existence the school has done excellent work and has established some striking facts. We need not recall to our readers the proof of the mosquito theory of malaria that was given to the medical world by the *experimentum in corpore vili* at the hands of Dr. L. W. Sambon and Dr. G. C. Low by their sojourn in the Roman Campagna at the most malarious season of the year in a mosquito-proof hut, owing to which precaution they remained free from the disease and not only so but in robust health. And this connexion between malaria infected mosquitoes and the disease in man was also proved by the demonstration that the former transported for a great distance into a non-malarial country could by their bites then infect human beings here. Another pupil of the school, Dr. A. Castellani, discovered the association of a trypanosome with sleeping sickness. Still another research by another pupil demonstrated a new species of schistosomus. Important researches, moreover, are being carried on as regards the causation and the prevention of beri-beri. Such are a few of the results that have been gained by the research work of pupils of the school. But in addition to the above research work, and even more important, is the educational curriculum that has led, and is leading, to it. Accommodation is provided for about 12 resident pupils, whilst 40 students can be instructed in the laboratory. There are three sessions, each of three months, held at the school. During these a most thorough laboratory course is carried out by the medical tutor, whilst the students have an opportunity of personally becoming conversant with many of the diseases that they will subsequently meet with in their career in the tropics. Already over 500 students have passed through the courses. Again, it may be mentioned that provision is made in the hospital for the admission of sufferers from tropical diseases who are unable to afford the luxuries of a nursing home. Finally, the work of the school is being supplemented by the establishment of laboratories in several colonial medical centres, such as Kuala Lumpur, Ceylon, and Hong-Kong. It is thus seen what a void in our system of medical education this school and the Liverpool School of Tropical Medicine are filling. Formerly the medical officer proceeding to his work in tropical climates had first of all to learn it in those regions; now he can proceed thither having first mastered the elements of this portion of the medical art. England is the great colonising country of the world; how great, then, is the necessity for the various deadly diseases to be understood fully by those of her sons who proceed to the colonies, the home of these diseases. We cordially wish this school and its staff the fullest measure of success that will doubtless in the future accrue to their endeavours. But in order to insure this object funds are necessary and we feel sure that the British public, once it is alive to the great benefits which the school is conferring, will not be backward in supplying them. As the Duke of Marlborough has stated in a public appeal, an increasing number of our kith and kin are annually required to carry on the work in the tropics, where the white man's burden is the heaviest, and it is undoubtedly a matter of Imperial importance that a knowledge of the etiology and treatment of the diseases to be met with in the tropics should be obtained. The London School of Tropical Medicine should not be hampered in its work by the shackles of debt and we are glad to learn that since Wednesday evening its coffers have been enriched by upwards of £10,000.

THE MEDICAL SOCIETY OF LONDON.

THE President and Council of the Medical Society of London will give a conversazione in the rooms of the society, 11, Chandos-street, Cavendish-square, W., on Monday next, May 15th. There will be a reception by the President at 8.30 P.M., when the Fothergillian medal will be presented by the President to Sir Frederick Treves, G.C.V.O., LL.D., F.R.C.S. The oration will then be delivered by Mr. Henry Morris who has taken as his subject the Financial Relations existing between the London Hospitals and the Associated Medical Schools and the Bearing of these Relations on Medical Education in London. At the conversazione there will be smoking and music by Pitman's Blue Viennese Orchestra.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

THE Lord Mayor of London has announced a Mansion House meeting to be held in aid of the work of the above-mentioned association on Wednesday, May 17th, at 3 P.M. The association is so well known to our readers that we need not refer to it at length here, but it may shortly be said that its chief work consists in measures for improving prophylaxis by advocating various hygienic measures and by the dissemination of literature to educate and to advise the public. With regard to treatment, the association is doing good work in endeavouring to make it plain that certain cases only of tuberculosis—namely, those in an early stage—are fitting subjects for sanatorium treatment. The work of the association is much hampered for want of funds and at the meeting in question an appeal will be made for £10,000. To quote the words of the notification, "Scientific research during the last half century, and especially during the last 20 years, has made plain the conditions which favour the spread of the disease and has shown how largely it is preventable." This is a true statement and one which should bring home to every mind the necessity for not allowing the good work which the association has already done to be more or less thrown away by a continuation of that work being hampered for want of money.

THE medical officer of health of the Cape Colony states that for the week ending April 15th the condition of the colony as regards plague was as follows. At King William's Town one case of plague, a native female, the wife of the patient reported during the previous week, was discovered. At East London three cases were discovered—namely, two coloured males and one European male. Plague-infected rodents were found at Port Elizabeth, Uitenhage, and East London and at the last-mentioned town there were also found two plague infected cats. In other districts there was no case of plague in man or other animal. As regards Hong-Kong, a telegram from the Governor received at the Colonial Office on May 8th states that for the week ending May 5th there were eight cases of plague and seven deaths from the disease.

THE second annual meeting of the Rural Midwives Association will be held at 66, Ennismore-gardens, London, S.W., on Thursday, May 18th, at 2.45 P.M., the Earl of Harrowby in the chair. Dr. George Reid, the county medical officer of health of Staffordshire, Mr. G. H. Fosbroke, the county medical officer of health of Worcestershire, and Dr. Thomas Savage, of the Warwickshire county council, are expected to address the meeting.

THE annual general meeting of the Dermatological Society of Great Britain and Ireland will take place at 11, Chandos-street, Cavendish-square, London, W., on Wednesday, May 24th, at 4.30 P.M., Dr. Henry Waldo, the President, in the chair. Professor McCall Anderson will deliver an oration entitled "A Plea for the More General Use of Tuberculin by the Profession." Members of the medical profession interested in the subject of the oration are invited to attend the meeting.

THE University of London provides courses of advanced lectures in physiology and the first of a course of three on Carbohydrate Metabolism was delivered by Dr. F. W. Pavy on May 9th at the Physiological Laboratory of the University, South Kensington. The remaining two will be delivered at 5 P.M. on May 16th and 23rd. There is no fee for the lectures and cards of admission may be obtained on application to the Academic Registrar.

THE next meeting of the Edinburgh University Club of London will take place at the Criterion Restaurant on Wednesday, May 24th, at 7.30 P.M., when the Right Hon. Lord Robertson will occupy the chair. Among those who have accepted invitations from the club are the President of the General Medical Council, the President of the Royal College of Surgeons of England, and the Director General of the Army Medical Service.

THE position of president-elect of the Medico-Psychological Association having become vacant by the resignation of the late Sir John Sibbald the council of the association at its last meeting unanimously elected Dr. Outterson Wood to the vacancy. The election has been accepted by Dr. Wood who will therefore become President at the annual meeting in July next.

Professor W. Osler has departed from the United States to take up his residence in Oxford as Regius Professor of Medicine. 500 physicians gave him a farewell banquet in New York and presented him with a copy of Cicero's "De Senectute" in allusion to a much paragraphed and much distorted version of his recent address at Baltimore.

THE next meeting of the Society for the Study of Disease in Children will take place at 11, Chandos-street, London, W., on Friday, May 19th, when Dr. Henry Ashby of Manchester will deliver the Wightman lecture on Some of the Neuroses of Early Life. The meeting is open to all members of the medical profession.

AT a recent meeting of the United Grand Lodge of English Freemasons Mr. W. H. H. Jessop, F.R.C.S. Eng., Mr. Ernest Clarke, F.R.C.S. Eng., and Dr. H. G. Thompson were among the new Grand Officers appointed. Mr. T. H. Openshaw, F.R.C.S. Eng., received the honour of past grand office.

Sir Francis Laking, Bart., G.C.V.O., physician-in ordinary to the King, who accompanied His Majesty upon his recent visit to France and French possessions, has been appointed a grand officer of the Legion of Honour.

The King has appointed Mr. Charles E. Truman, M.R.C.S. Eng., to be dentist to His Majesty's household, *vice* Mr. E. T. Truman, deceased.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

(FROM OUR OWN CORRESPONDENT.)

THE visit of British physicians and surgeons to Paris began auspiciously in perfect weather. The opening reception, which was organised by the University of Paris, took place at the Sorbonne on Wednesday evening and was fully attended by the visitors, and in many instances by their wives and families. The absence of M. Casimir Perier, who was, it is understood, too ill to deliver his promised address, was the subject of much regret, but the interchange of congratulations between the University Reception Committee and the London Executive Committee supplied sufficient speeches for the occasion, and, it may be added, their speeches were of a very happy character. Everything promises a most successful reunion.

Two small volumes or pamphlets have been published expressly for the benefit of the British medical men now on a visit to Paris. One, in French, consists of a short history of the ancient Faculty of Medicine and College of Surgeons of Paris. It is beautifully printed and illustrated and commences by recording that Charlemagne advised German youths to study medicine in Paris and invited an English teacher over to give them lessons. This was the philosopher and theologian Alcwin or Alcuin, who was born at York in 735. The little volume recalls this fact with pleasure, for it shows that from the first the University of Paris contracted a debt of gratitude to an English scholar. The work then traces, with quotations from old title deeds, charts, &c., the growth of the school of medicine and surgery, gives pictures of the various buildings which they occupied, and reproduces certain seals, portraits, headings of theses, and other engravings. Some of them are real works of art.

The other pamphlet is issued in English and is written by M. André Mésureur, the son and chief of the cabinet of M. Mésureur, director of the poor relief administrations of Paris (Assistance Publique). It is a practical guide with blank leaves for taking notes. A large coloured map of Paris serves to indicate the position of all the hospitals and of all the other places and offices that relate to the relief of the poor. Then there is a brief description with a photographic illustration of each of the principal hospitals. This is preceded by a short chapter giving a description of the Assistance Publique. It shows how the town of Paris assumes the responsibility for all the services of poor relief and the advantages that this affords in the organisation of the hospitals as representing the practical side of medical education at the University of Paris. M. André Mésureur also briefly alludes to the economic advantages of purchasing wholesale and in one single transaction the meat required for all the hospitals, asylums, and such institutions. These advantages exist likewise in all other respects, such as the bread-supply, milk, medicines, furniture, beds, and so on. Finally, the uniting together of all the poor relief services renders it more easy to ascertain particulars about the hospital patients and prevents the abuse of the hospitals by those who can afford to pay. The cost of all these services is defrayed to a large extent out of the income of the city. The last subvention from the city amounted to £1,120,000. Then there is a direct tax for the relief of the poor levied on every occupied seat at the theatres. This brings in £140,000. The other sources of income are not from taxation. £260,000 were received from lands, houses, and personal property. Fees and gifts from sick patients amounted to £208,000. With other smaller sources the income exceeds £2,000,000 annually for poor relief. The principal expenditure is as follows: hospitals, £820,000; outdoor relief, £500,000; almshouses, £400,000; and foundlings, £560,000. These few figures and facts set forth the great difference between the French system and the British voluntary efforts and the British Poor-law. To study on the spot these very important problems will be the more useful as the method of solution attempted in Paris is so completely different from that employed in England.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER XI.[1]

THE POOR-LAW AND MEDICAL SERVICE.

Poor-law Medical Service in England.—Good Work of Dr. Joseph Rogers.—Poor-law Medical Service in Scotland.—The Case of Mr. Lamont.—Parish Councils and Arbitrary Dismissals.—Scottish Poor-law Medical Association.

THE Poor-law medical services of England, Scotland, and Ireland, like the sanitary services of the three countries, are on different bases and with respect to the two last-named countries the abuses that are to be found in their working are gross. The grievances of the English service run a risk of being overlooked because they are of a less sensational character. They are none the less real.

The Poor-law Medical Service in England.

The English Poor-law medical officer's position, although it is good by comparison with that of his Scottish and Irish brethren, is not so perfect that there is anything ungracious in suggesting that it is open to many improvements. The position which it has is the outcome of the work of Dr. Joseph Rogers, founder and first president of the Poor-law Medical Officers' Association. Rogers, one of the numerous brothers of the well-known economist the late Professor Thorold Rogers, was a supernumerary medical officer in the parish of St. Anne's, Soho, at the time of the outbreak of cholera in that district of London in 1855. His work was rewarded by his appointment in the following year as medical officer to the Strand workhouse. Through his brother, as well as from natural taste, he became associated with the school of social reform of which Cobden and Bright were the leaders and as soon as he found himself in responsible charge he set to work, with the cordial coöperation of Thomas Wakley, the editor of THE LANCET, to improve the system of medical relief to the sick poor. The nursing, the diet, the accommodation, and the general amenities of life in workhouses and workhouse infirmaries were fair objects at that time of stringent criticism but Rogers's reforming zeal soon brought him into conflict with the guardians of the parish. The President of the Poor law Board, the extinct Government department then responsible for the administration of the Poor-law, took the side of the supine authorities and Rogers lost his berth. In 1872, however, he was elected medical officer of the Westminster Infirmary, where he pursued the same humane and enlightened tactics. Complaints were again made of him as a troublesome fellow but this time the President of the Poor-law Board found that he was in the right and his admirers presented him with a testimonial. Perceiving that the same obstacles would be brought to bear upon any of his colleagues who might be inspired with similar humane ideas to his own, he founded the Poor-law Medical Officers' Association of which he was the first president.

His hopes that this association would grow into a powerful union have been but partially realised, because progress in the general sanitation of the country has taken place along other lines, but the efforts of Rogers and the small band associated with him count for much in the fact that the grievances of Poor-law medical officers in England are not so pronounced as they are in the other divisions of the kingdom. They are not oppressed by Bumbledom to the same extent and their position is altogether a more independent one. Still they are not without legitimate causes of complaint. The salaries of the medical officers to the Poor- [illegible] their exiguity is not counter- [illegible] r private practice. The life is [illegible] the clinical material presents no features of interest to scientific medicine, though this is a state of things which is tending to improve. The salaries of parochial officers are also small but they are punctually paid. The fact that the Poor-law officer is, as a rule, the social superior of the guardians under whom he serves now and again results in annoyances, but a hard-working and tactful practitioner escapes most of the unpleasantness and the competition for the posts shows that they have distinct attraction. The explanation of this is probably that in some places the possession of Poor-law appointments brings compensating advantages in practice, a view that is strongly combated by those to whom no such advantages have accrued and who contend that the more substantial class of patients have an objection to employ the "parish doctor." Wherever in the social scheme we get competition for posts and complaints of inadequate remuneration going together there will be a difference of opinion as to the reason of such an apparent violation of the laws of supply and demand, and the fact that many desire to fill the berths will be employed as an argument to close the mouths of those who would assert that the berths are not worth filling. As a matter of fact, in the case of the Poor-law medical officer no general rule applies, as the scale of pecuniary return is not uniform and the attitude of the public and the Poor-law guardians is not the same all over the country.

---

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., and X. were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877), 15th (p. 1017), 22nd (p. 1089), and 29th (p. 1151), and May 6th (p. 1218), 1905, respectively.

It is an undoubted hardship upon Poor-law medical officers that in many instances the salaries remain the same as they were 40 years ago, in spite of the largely increased cost of living generally and of medical education and medical practice in particular. All medical men in general practice are suffering from the fact that their professional fees have remained for the most part stationary while everything incidental to medical education and practice has gone up in price. but Poor-law medical officers have an easily demonstrable claim upon the public for better terms: The special fees for operations were fixed in 1847 and have not been revised since. There are numerous operations, the outcome of advancing surgical knowledge, for which no special allowance can be obtained without the consent of the guardians, and there is no fee provided by law for giving anæsthetics. As far back as July, 1902, the President of the Local Government Board was asked in the House of Commons to explain why no provision was made for the administration of anæsthetics when operations had to be performed by Poor-law medical officers on sick paupers at a distance from a hospital or workhouse infirmary; and why no alteration had been made in the scale of fees allowed for special operations performed by Poor-law medical officers since the year 1847, many important operations, which have now become general, not having been placed on the original list. The President of the Local Government Board (at that time Mr. Long) replied that the Board recommended that in ordinary circumstances a case in which a serious operation was required should not be treated in a workhouse or at the patient's home but should be sent to a public hospital. This was the position taken up by the Board eight years previously in a circular letter issued to all boards of guardians, though in that letter it was stated that in any case, when it was not practicable to send the patient to [illegible] n the operation was not of a serious cha [illegible] might sanction the payment to the medical officer of a reasonable sum in respect of any assistance which it was necessary for him to obtain for the administration of an anæsthetic. Mr. Long went on to point out that it had been the invariable practice of the Board to give its sanction to reasonable payments proposed to be made by boards of guardians to medical officers in circumstances of the kind referred to, and added that he was unaware that difficulties had been experienced in connexion with the scale of fees to Poor-law medical officers for operations, but that if representations were made to him showing alterations to be required he would give the subject careful consideration. How Mr. Long came to be unaware of the dissatisfaction among Poor-law medical officers at the scale of fees for operations is difficult to understand but during his tenure of office as President of the Local Government Board he proved himself in many ways an enlightened advocate of medicine and we may feel certain that his want of information was real and not merely official. With his opinion that in ordinary circumstances patients requiring serious operations should not be treated in their homes all medical men are in agreement; it is not so certain that the recommendation to draft every important surgical case to a hospital in contradistinction to an infirmary is so sound. But the promise of careful consideration of the whole subject has not been kept by the Local Government Board. In December, 1902, encouraged by Mr. Long's kind words, the Poor-law Medical Officers' Association addressed a memorial to the Local Government Board pointing out that in spite of the Local Government Board's circular letter of 1894 guardians almost invariably declined to ask the sanction of the Board for the payment to medical men of fees for extra services, so that the Poor-law medical officer when requiring to perform an operation upon a pauper patient has either to obtain the unpaid assistance of a brother practitioner or to pay the anæsthetist's fee out of his own pocket. The memorial suggested that a fee of £1 should be paid for the administration of an anæsthetic, the payment being restricted, if thought well, to those instances where a certificate of its necessity is forthcoming from a second medical practitioner, while operations, now common procedures, like laryngotomy and tracheotomy, should be paid for at the rate of £2. The highest payment for operations on the present scale to Poor-law medical officers of health is £5, which is the legal fee for the treatment of strangulated hernia, of compound fractures or dislocations of the thigh or leg, and for major amputations. To this list the memorial proposed to add the operation of trephining and the treatment of a compound fracture of the patella, while for simple fracture of the patella a fee of £3 was asked. The memorial acquiesced in the general proposition that serious cases should be treated as far as possible in a hospital but dwelt upon the difficulties of Poor-law medical officers in country districts where it may be often impossible to move a patient to a hospital. In such cases the particular injustice done to the Poor-law medical officers in making them attend the patients without extra fees is aggravated by the fact that many hospitals receive from boards of guardians payments for the réception of cases for operation—the scale of which payments, by the way, might well be scrutinized. To this memorial the Poor-law Medical Officers' Association has received no reply. This is distinctly unfair to the association in view of Mr. Long's sympathetic words in Parliament and must necessarily confirm boards of guardians in their intention not to take any steps to grant extra fees.

The attitude of boards of guardians towards their medical officer differs considerably—in some districts the work is harmoniously carried on and in others it is not. In certain parts of the country boards of guardians have refused to raise the salaries of their medical officers, being public vaccinators, on the plea that the last Vaccination Act has increased the public vaccinator's fees, and some guardians have been attempting, where contracts have terminated, to reduce salaries on the same grounds. This is, of course, quite unfair. To begin with, any reduction of the salaries of Poor-law medical officers must be illogical considering the increasing work that now has to be done by them and the enhanced expenses of medical education and medical practice. In the second place, the emoluments received by public vaccinators, who are also district medical officers, vary so much that no general conclusion can be drawn from them. In some urban districts the public vaccinator's fees may pay him well. in some rural districts they certainly do not. But urban and rural districts alike, a request by medical officers for a higher salary based upon an increase of work and an increase of expenses is generally met with a refusal at the hands of the guardians, who quote in support of their action the vaccination fees.

Thus it will be seen that the grievances of the Poor-law medical officers in England are quite genuine, if not exactly glaring as they are in Scotland and Ireland. Their work has increased and their expenses have increased, while their salaries have remained the same, not without threats of curtailment. Yet there is considerable competition for the posts, so much that favouritism, it is alleged, takes place in respect of the appointments. How is this to be explained? Firstly, the pay offered by the unions, poor as it is, is better than that offered by medical aid associations. Secondly, the posts sometimes carry indirect advantages. There are readers of THE LANCET who may not endorse the statement, but it seems impossible to escape from the conclusion that these posts are accepted in certain instances because they provide the holders with a publicly guaranteed introduction to the neighbourhood. That such should be the fact is regrettable. Honest work should be worth proper payment, it should never have to look for indirect emolument, and one class of medical men should not be tempted to use their official position to the detriment of their brethren. These things are admitted; but it must also be admitted that the appointment of Poor-law medical officer is a good deal coveted.

The Poor-law Medical Service in Scotland.

In Scotland the public medical service, the service which is intended to meet the wants of the indigent poor, is in urgent need of reform. To go no further back than six years attention was called in 1899 to the scandalous condition of affairs by the *cause célèbre* of Mr. J. Lamont, the medical officer of South Uist,[2] whose vicious treatment by the authority to whom he owed his appointment was made the subject of Parliamentary interference. Mr. Lamont was dismissed summarily from his office by the parochial authority, his dismissal being apparently due, at least to a great extent, to his insistence on the closure of a school during an epidemic of infectious disease. In this he had the support of the Local Government Board of Scotland, but that availed nothing when, as a practical rejoinder, the parish council terminated his appointment. Following on his dismissal from office Mr. Lamont's oppressors in South Uist raked up the fact that he had some considerable time ago vaccinated certain children whom, owing to press of work and length of distance (or want of roads), he had certified as successfully vaccinated without paying a second visit, his certificates being based on what he regarded as trustworthy information. This he did in his inexperience and in the absence of official guidance as to his procedure, but it appears that the practice is by no means unknown in the northern counties of Scotland. It is an evil practice and no one should attempt to justify it, but the prosecution of Mr. Lamont was undertaken in a manner warranting the theory that its origin was to be sought not in regard for the law or in zeal for vaccination but in vindictive spite. It was the manner in which Mr. Lamont was treated that led to the publicity which may yet have a fortunate issue, as it has called attention to the grievances of the Poor-law medical service of Scotland, especially of those whose duties lie in the highlands and islands. Mr. Lamont was arrested at midnight in his mother's house on the allegation that he had absconded from justice; he was imprisoned for two days, was escorted from Glasgow to South Uist by the police, was imprisoned a second time, and on release was subjected to a fresh warrant of arrest in London. The nature of this persecution led to very downright speaking upon the existing conditions of the Scotch Poor-law medical service in the press. Then came action in Parliament. Sir Charles Cameron, in Committee of Supply on the vote for the salaries and expenses of the office of Secretary for Scotland, called attention to the case and, when the Lord Advocate defended the prosecution as right and justifiable upon the evidence, several influential Members of Parliament spoke in strong criticism of this view, asserting that Mr. Lamont had been harshly used and was entitled to some sort of compensation. The Lord Advocate then agreed that the arrest should not have been ordered and undertook to censure the Procurator Fiscal, when the Prime Minister delivered an important pronouncement. He expressed his regret that in the present state of the law medical officers in Scotland had no protection against the arbitrary action of the local authorities and thought that the Government ought to possess the power to protect medical officers whose duties must occasionally bring them into collision with, and subject them to the arbitrary action of, those who were their employers and against whom at the same time it might be their duty to proceed. He pointed out that as the law stood no Vote in Supply could affect the matter at issue one way or another, directly or indirectly, but he discussed the question whether any action could be taken against the local authorities who, it appeared from the discussion, were the real villains of the piece. The Lord Advocate at the close of the discussion announced that he had the authority of the Prime Minister to say that he considered himself bound to look into the question of compensation.

Mr. Balfour's words raised all the issues admirably because he so clearly distinguished between the great grievances of Mr. Lamont and the anomalous position of all Poor-law medical officers in Scotland whereby such things became possible. Mr. Balfour definitely committed the Government of that day, which remains the Government of this day, to look into the whole question of the position of parochial medical officers in Scotland. A practical result followed upon this important debate, for Mr. Weir moved Parliament for a return showing the number of medical officers dismissed by parish councils in each crofting county during each year from 1895 to 1901 inclusive, name of the parish council, and the cases in which a cause of dismissal was assigned. The return was issued as follows:—

Return of Medical Officers Dismissed by Parish Councils since May 15th, 1895.

County and parish	Number of medical officers dismissed	Date	Whether cause for dismissal was assigned
Argyll			
Kilfinichen	1	1897	No
Caithness			
Halkirk	1	1896	No
Inverness			
Ardersier	1	1902	Yes
Barra	1	1898	No
Croy	1	1902	Yes
Petty	1	1902	Yes
S. Uist	1	1898	Yes
Orkney and Shetland			
Lady	1	1899	Yes
Evie	1	1898	No
Rousay	1	1900	No
Stronsay	1	1898	Yes
Ross-shire			
Kincardine (parish of)	1	1896	No
Uig	1	1899	No
Sutherland			
Durness	1	1898	No
Kildonan	1	1899	No
Loth	1	1899	No

It will be seen that in seven years—i.e., from 1896 to 1902—16 medical officers were dismissed by their parish councils, 10 of whom received no reason whatever for the termination of their engagements. Upon this return being made public a wide feeling of insecurity was felt among Scottish parochial medical officers which was not decreased by looking closer into the facts. The return deals only with

petty annoyances and wounded by the advantage taken of their subservient position many medical officers in the Scottish Poor-law service have been compelled to resign office in the interest of their honour and of the dignity of their profession.

The composition of the parish councils is largely responsible for this unfortunate state of affairs. During the 50 years of the existence of the old parochial boards, which were composed of the most influential members of the parish, the medical officers received proper treatment, but on the passing of the Local Government Act in 1894, when the membership of the parish council was thrown open to all ratepayers, a different spirit began to prevail. The parish councils, especially in the crofting districts, are now usually composed of the parish clergy (Established and Dissenting), lay preachers, missionaries, small shopkeepers, crofters, and fishermen. These oddly comprised bodies, more than half of whom are without education—at any rate, without any education that can enable them to appreciate the methods of self-respecting and efficient medical practice, the proper rate of pay, or the proper methods of behaviour—have unlimited power over the medical officer and in many cases, it would seem, do not fail to use it. While rendering his tenure of office miserable they can and do dismiss him without a reason. This is an extraordinary position of affairs and one that calls for the measure of reform virtually promised some years ago by Mr. Balfour. Inspectors of the poor and other parish officials cannot be dismissed without the sanction of the Local Government Board of Scotland and the medical officers ought to enjoy the same security. They ought to be able to feel that their work and conduct will be judged by a competent and unbiased public department and not by a group of their neighbours, mostly their inferiors in station and knowledge.

Insecurity of tenure, however, is not the only drawback to the service. In many cases, it is stated, exorbitant house rents are charged and the salary is not commensurate with any heavy expense in rent unless the private practice be lucrative. This it is not likely to be in sparsely inhabited neighbourhoods where patients live far apart and where horses have to be kept to meet their wants. Moreover, the cost of medical education has increased and the working expenses of the medical officer have become heavier of late years but the salaries given have not been raised and, while never anything but small, now bear no sort of proportion either to the medical officer's needs or to the hardships that he has to undergo. During sickness, or temporary absence from the parish for a holiday or upon private business, the medical officer has to provide a substitute who may cost him from £4 4*s.* to £5 5*s.* a week with travelling expenses and board. Other parish officials—*e.g.*, ministers, Poor-law inspectors, and schoolmasters—can usually get a free and even an extended holiday, and the same reasonable facilities for rest and recreation should be granted to the medical officers not as a favour but as part of their contract for service. We are constantly told that the extreme poverty of certain districts of Scotland forbids more generous payment to the medical officers. The proper deduction from this premiss, of course, is that the State should assist the community that cannot assist itself, but the premiss is not secure from contradiction. The financial condition of highland and island parishes has materially improved of late years, while the medical officer's position and absurdly inadequate salaries, fixed by the old parochial boards, remain what they were 20 years ago despite the increased expenses of the medical man's education and the far more costly equipment of medical practice.

---

[2] Vide the *Times* Parliamentary Report, July 15th, 1899.

The Scottish Poor-law Medical Association upon these grounds is prepared to advise medical men who are thinking of applying for parochial appointments in the highlands and islands of Scotland to communicate with the out-going medical officer on the following points:—

1. The character and general attitude of the parish council towards the medical officer.
2. The house accommodation and the rent of the house.
3. The adequacy of salary as medical officer to the paupers.
4. The arrangements for holiday and sick leave.

By ascertaining from the late appointee whether the vacancy has recurred owing to his arbitrary dismissal or to a resignation forced upon him by the arduous circumstances of the post candidates run no risk of accepting unfair terms to the damage of their own interests and of the honour of the medical profession. If the younger generation of medical men in Scotland were to follow the suggestion made to them they would find that in many instances the berths to which they aspire are badly paid, or, at any rate, that the salary is incommensurate with the expenses. The following concessions secured by legislation are necessary, in the opinion of the Scottish Poor-law Medical Officers' Association, to make the office of a Poor-law medical officer in the highlands and islands of Scotland worth retaining:—

1. The right of appeal to the Local Government Board of Scotland against unjust dismissal.
2. Free official residence.
3. Increased salary, chiefly in the form of increased fees for attendance on midwifery cases and cases of serious surgical injury, and for the certifying of lunatics.
4. Annual free holiday of reasonable length and a free substitute in case of sickness.
5. Superannuation allowances.

A departmental committee of the Local Government Board, after a close inquiry, has recommended the granting of the first two reforms, and a Bill has been drafted embodying the recommendations.

It is possible that there will be no long delay before the Bill becomes law, but until that day the association suggests that young medical men should not accept appointments in the highlands and islands of Scotland as acquiescence in the existing wrongful system assists in keeping up unjust and unsatisfactory conditions. These proposals for a boycott of the parochial medical service are drastic but it is doubtful if they would succeed. It must be difficult to secure the necessary unanimity of opinion among young medical men anxious to make a start, whose natural desire to support themselves is backed by a family circle guiltless of any professional sentiment. At the same time all must agree that medical men must be provided for the sparsely populated districts of Scotland at proper rates of remuneration and under conditions which they can accept without loss of dignity or risk of unjust treatment. It is to be hoped that Mr. Balfour's promise of reform will not be lost sight of either by the medical profession in Scotland or medical men in Parliament. State aid is required. The simplest form in which that aid could be granted would be by the erection of the Poor-law medical officers into assistant medical officers of health. To such officers, properly salaried, might be confided all the local duties of medical attendance upon infectious disease, of inspection of schools, workshops, bakehouses, and abattoirs, and they might be put in charge, under the county medical officer, of the necessary statistical returns of public health. There is no need in Scotland for a sanitary official distinct from a Poor-law officer, and the care of the sick poor could best be undertaken by those who are responsible for the sanitation of their environment—only money, not much of it, being wanted to carry out this reform.

(*To be continued.*)

THE EARTHQUAKE IN THE PUNJAB.

A NARRATIVE BY A MEDICAL SURVIVOR.

DHARMSALA and the Kangra Valley were visited by an exceptionally severe earthquake on April 4th. It commenced about 6.20 A.M. and appeared to travel in a direction from south east to north-west. Every house in the station was more or less affected, the majority falling in completely and instantaneously, whilst a few stood partially, and in one house (that of Captain Bateman-Champain, 1st Gurkha Rifles) the roof of one room only fell in. There was no time for escape and with the exception of a very few all who were not killed were more or less seriously injured. The killed included 30 Europeans (which represents a very large proportion, nearly 50 per cent., of our small European population). There were also killed 63 of the 1st Gurkha Rifles and 135 of the 7th Gurkha Rifles. The severely injured included nine Europeans, 28 of the 1st Gurkha Rifles, 55 of the 7th Gurkha Rifles, and three reservists. The slightly injured included 15 Europeans, 73 of the 1st Gurkha Rifles, and 117 of the 7th Gurkha Rifles. The number of deaths of natives in the district may probably be reckoned in tens of thousands. First aid to the wounded was rendered as promptly as possible by Major P. Hehir, I.M.S., with the help of two hospital assistants in the 7th Gurkha Rifles; and by Major H. M. Earle, I.M.S., with the help of one hospital assistant in the 2nd Battalion of the 1st Gurkha Rifles. Major Hehir fortunately escaped without being injured and Major Earle with comparatively slight injuries, otherwise it is awful to contemplate the horrors that would have been added. Luckily, also, the surgical appliances, &c., had mostly escaped much damage. The work of rendering first aid was commenced at the time of the disaster and was completed at 11 P.M. the same night. The element of shock naturally entered very largely into the cases. The majority of the wounded are progressing very favourably.

The following is a list of the chief cases of injury: one British officer sustained fracture of the internal table of the skull and compression of the brain; one British officer sustained injury of the pericardium and scalp wound; three British officers suffered from fairly severe scalp wounds and general contusions; and two ladies sustained simple fractures of the thigh. All the above are doing well. One Gurkha officer suffered from crushing of the breast and lungs, laceration of both ears, five extensive scalp wounds, concussion of the brain, and comminuted fracture of the clavicle; he is, however, doing well. Six Gurkha officers sustained various injuries, including broken ribs, scalp wounds, and extensive contusions. All are doing well.

Injuries of the following varieties were noted among the rank and file: a case of compound comminuted fracture of the thigh for which amputation was performed (the patient died); a case of fracture-dislocation of the spine and fracture of the pelvis with rupture of the bladder; a case of fracture-dislocation of the spine (this patient has now developed pulmonary tuberculosis); a case of fracture-dislocation of the spine without further complications (this patient is doing fairly well); a case of extensive destructive crushing and laceration of the front of both legs, exposing several inches of the tibiæ (this patient developed tetanus);

a case of compound comminuted fracture of the right leg tearing the anterior tibial artery and nerve (this patient also developed tetanus), five cases of fracture of the base of the skull (of these patients one died two are doing well and two are left with several cranial nerves paralysed), a case of uncomplicated fracture of the pelvis (this patient is doing well), a case of fracture of the pelvis with rupture of the bladder (this patient is doing fairly well), nine cases of fracture of the ribs (in one of these there was much subcutaneous emphysema and the patient died, in another there was subcutaneous emphysema and pneumonia occurred as a complication but the patient is doing as well as can be expected, two others were also complicated by wounds of the lungs), two cases of dislocation of the spine, both of which were reduced and the patients are doing well, a case of dislocation of the hip joint which was reduced and the patient is doing well, two cases of simple comminuted fracture of the thigh five cases of simple fracture of the thigh, six cases of compound fracture of the leg a case of compound comminuted fracture of the humerus the ends of which were wired and the patient is doing well, two cases of simple fracture of the arm five cases of simple fracture of the clavicle two cases of simple fracture of the forearm, a very extensive and severe scalp wound two cases of injury of the pericardium with hæmo pericardium a case of injury of the pericardium and heart, and five cases of injury of the kidneys (three of these patients died)

As regards the cases that developed tetanus the symptoms commenced on the ninth day after the earthquake Antitetanic serum was administered on the tenth day in curative doses but had no effect All the other patients suffering from compound fractures and crushing wounds have been given prophylactic doses of antitetanic serum and so far have shown no symptoms of tetanus The complicated case of fracture of the pelvis is interesting in that after laparotomy about a cubic inch of the left side of the arch of the pubis was found separated and penetrating the bladder

Most of the fractured thighs have been treated by simple horizontal extension and most of the compound fractures are doing well under conservative treatment In some of the cases of injured kidney urine was voided highly mixed with blood and in others there was almost complete suppression of urine One patient developed uræmia and was treated by diaphoresis and saline injections but finally succumbed The cases of fracture dislocation of the spine were swung and reduced as far as possible and then put up in plaster of Paris

Mr W Watson Cheyne s view that shock is due to a state of exhaustion of the medulla and spinal cord, tending to a great reduction in the vital activity generally and resulting from severe injury of the peripheral ends of the sensory and sympathetic nerves, appears to receive valuable confirmation from the cases of wounded in the earthquake though vasomotor paralysis, no doubt was also present in many cases

There are now five medical officers working on the military side of the station—namely Major Hehir, Major Earle Captain H E M Douglas V C R A M C Lieutenant G H Whale I M S and Lieutenant A F Pilkington I M S Colonel D O Sullivan R A M C also lent valuable aid for some days Four medical officers are working on the civil side—namely, Major Lane Major S Browning Smith Major G MacIver C Smith and Captain W E McKechnie all of the Indian Medical Service with the aid of assistant surgeons and hospital assistants

The Gurkhas both officers and men worked splendidly in extricating the wounded and dead There were several very hard cases of people who were on the point of leaving the place losing their loved ones whilst others were fortunate in having just left Several people who had most, and perhaps all of their money invested in house property are reduced to indigent circumstances and I believe that only one tea factory is left standing in the district Provisions were very short at first but supplies were quickly sent up by the civil and military authorities as was also medical aid Pioneers and sappers and miners have been and are, doing yeoman service in extricating bodies of men and animals and private property from the mines and in repairing roads bridges, &c

Cases of extraordinary vitality were observed, some persons having been dug out alive after three and four days and one man after five days A dog was unearthed alive after having been buried for 11 days All are in tents Fortunately the weather has been fine with the exception of one or two severe thunderstorms Minor shocks of earthquake occurred at frequent intervals during the night following the disaster and subsequently the intervals gradually increased Now we only get one a day Geologists state that the Himalayas are of comparatively recent formation and that there is no reason to doubt that the forces which brought their folds into existence are yet in action It seems a reasonable theory that somewhere under the Kangra valley and Dharmsala there occurred a caving in of some ill supported portion of the earth s crust and possibly the proximity of Dharmsala to the high ranges may have had something to do with the severity of the shock However this may be it becomes an important question and a very enervating one to those residing there, whether further earthquakes will occur in other hill stations in the Himalayas The obvious indication seems to be that buildings should be constructed of lighter material than they are at present and that no double storeyed houses should be built

Dharmsala April 19th

THE GERMAN CONGRESS OF INTERNAL MEDICINE[1]

(*Concluded from p 1232*)

Therapeutic Applications of the Röntgen Rays

Dr HOFFMANN (Dusseldorf) discussed the Treatment of Leukæmia and Pseudo leukæmia by the Roentgen Rays He said that the patient s general health improved the number of leucocytes decreased and the spleen became smaller In one case the skin became gangrenous three months after exposure to the rays It was remarkable that the patients continued to improve even after the termination of the treatment

Dr KRAUSE (Breslau) said that he had treated six cases of myelogenic and two cases of lymphatic leukæmia with the rays during several months He confirmed the favourable results obtained by Dr Hoffmann and drew attention to the fact that the discharge of uric acid was very much increased by the treatment In lymphatic leukæmia his results were not so good as in the myelogenic form In one case of pseudo leukæmia Dr Krause obtained a favourable result in another case there was no improvement

Dr LINSER and Dr HELBER (Tubingen) communicated a paper on the Influence of the Roentgen Rays on the Blood By experiments made on animals they ascertained that under the influence of these rays the leucocytes decreased and might even almost disappear from the circulation They were of opinion that the rays destroyed the leucocytes in the circulating blood They had been led to this opinion by the fact that after the leucocytes had totally disappeared from the circulation they were nevertheless still present within the spleen and the marrow of the bones The same result was obtained whatever part of the body was exposed to the rays and even outside the body the action of the x rays on the leucocytes might be observed in fresh or stained microscopical preparations The destruction of the leucocytes by the x rays produced toxic substances in the blood serum—the so called leucotoxins This leucotoxic serum when injected into animals also destroyed the leucocytes whilst the injection of normal serum made them increase The degree of efficacy of the Roentgen serum depended on the number of leucocytes destroyed and was therefore produced by their destruction At temperatures of 55° or 60° C the serum became inactive Probably the presence of nephritis in animals exposed to the rays was also caused by the leucotoxic substances Some degree of immunity was established in the animals exposed to the rays as after the first decrease of the leucocytes they again spontaneously increased although the irradiation was maintained Radium and ultra violet rays had no destructive action on the leucocytes similar to that which was possessed by the Roentgen rays The Roentgen rays moreover did not affect the red corpuscles

In the discussion some of the speakers deprecated the formation of exaggerated hopes as to the radiotherapy of leukæmia the overwhelming majority however were of opinion that the Roentgen therapy had a curative effect on the disease in a great many cases and in this respect exceeded all the other therapeutic methods. Success was not, however, invariably obtained because certain forms of the disease were resistant to the action of the rays.

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medicinische Wochenschrift* through whose courtesy it has been forwarded to us by our Berlin correspondent

Radio-activity of Mineral Waters.

Dr. **BERGELL** and Dr. **BICKEL** (Berlin) communicated a paper in which they described their researches on the Radio-activity of Mineral Waters. The mineral waters when freshly collected from the spring showed an emanation of radium, which, however, disappeared within a short time. Exported mineral waters were, therefore, free from radium, but it was possible to make them radio-active again by means of a solution of radium salts. Dr. Bergell and Dr. Bickel made their experiments with Kochbrunnen, a spring at Wiesbaden, the water of which contains chloride of sodium. This water when deprived of the emanation of radium retarded the digestion of albuminates, but after artificial restoration of the radio-activity it promoted digestion.

Dr. **BRAUNSTEIN** (Moscow) reported that by injection of radio-active water malignant growths were made to disappear, a fact which might be of the greatest importance in the treatment of cancer. The injection of radio-active water was preferable to irradiation because the deeper layers of the tissue might in this way become influenced or the radium might be applied to growths which were not reached by the rays. Apart from the destructive action of radium on the tissues its bacteriological action was of great importance, and its favourable influence on certain fermentative processes might possibly be used in the treatment of diseases of the gastro-intestinal canal.

The Secretion of Mucous in the Intestines.

Dr. **SCHUTZ** (Wiesbaden) said that the mucous discharge in the intestines differed very much in pathological conditions but that it was impossible to conclude from its quantity whether the condition was of nervous or of catarrhal origin. A nervous origin of a secretion of mucus was very rare; as a rule mixed forms occurred together. The quantity of epithelial cells in the mucus was proportional to the quantity of the latter.

In the discussion Dr. **SCHLESINGER** (Vienna) stated that in mixed forms of membranous enteritis and catarrhal colitis the mucous discharge sometimes contained a great quantity of leucocytes, sometimes only epithelium of the intestine without leucocytes.

Dr. **BICKEL** said that the mucous discharge was not produced by a mere nervous irritation of the mucous glands; like Professor Pawlow, he was of opinion that the mucous secretion was a prophylactic measure of the organism to remove injurious substances. He had found that when an injurious agent produced an abnormal discharge of mucus in the stomach it did not extend over the whole surface of the mucosa but was confined to the area affected by the agent in question. Electrical irritation of the mucosa of the stomach produced a discharge of mucus but not of the specific gastric juice.

Sleeping Sickness.

Dr. **ALBERT LORAND** (Carlsbad) read a paper which he described as a contribution to the Pathology of African Sleeping Sickness. He said that the features of the disease resembled those of myxœdema not only in respect of most of the clinical symptoms, including the apathy and somnolence, but also in the anatomico-pathological appearances, especially those observed in the central nervous system. As often happened with myxœdema, sleeping sickness was preceded by an infectious disease. In the case of sleeping sickness this infectious disease was trypanosomiasis, which presented most of the typical symptoms of hyper-activity of the thyroid gland—namely, hyperthermia, tachycardia, perspiration, diarrhœa, insomnia, and pruritus. In hyperthyroidia there was insomnia but in athyroidia (myxœdema) there was somnolence. It was well known that in most of the infectious diseases the thyroid gland was liable to undergo pathological changes which might be followed by degeneration. Dr. Lorand had an opportunity of observing the disease in a white officer who had returned to Europe from the Congo and in whose cerebro spinal fluid trypanosomata were found. In this case good results were obtained by the use of thyroid tablets, especially in the symptoms referred to the nervous system.

Among the many other subjects brought before the congress mention may be made of papers on the Circulation in Anæmic Patients, by Dr. **MOHR** (Berlin); on Nervous Tachypnœa, by Dr. **HOFBAUER** (Vienna); and on the Centrifugal Current in Sensory Nerves, by Dr. **KOHNSTAMM** (Munich).

THE DINNER OF THE LONDON SCHOOL OF TROPICAL MEDICINE.

A BANQUET was held on May 10th, with the object of liquidating a large debt which the London School of Tropical Medicine has unavoidably contracted. The gathering proved in every way a success. The chair was occupied by the man to whose foresight, inspired mainly by Sir Patrick Manson, the inception of the school is due—namely, the Right Honourable Joseph Chamberlain, formerly Colonial Secretary. The school was founded in the year 1899, its primary object being to afford instruction in tropical medicine to medical officers of the Colonial Service, and the committee of management of the Seamen's Hospital Society was invited to establish the school in connexion with its hospitals. The committee at once fell in with the suggestion but instead of the facilities for training being confined to those who had entered, or were about to enter, the Colonial Medical Service the school was thrown open to all medical practitioners who wished to obtain training in the subject of tropical diseases. The institution flourished from its commencement, but, with that kind of *τύχη ἀτυχής* which so often attends success, so many students sought admission that the laboratory originally built did not suffice and a large addition was rendered necessary. The expenses thus incurred laid a debt of £6000 on the school authorities, thus commencing the burden which it was the object of the banquet to relieve.

A representative company assembled, including Mr. Alfred Lyttelton, the Secretary of State for the Colonies, the Duke of Marlborough, Under-Secretary of State for the Colonies, Lord Rothschild, Sir Richard Douglas Powell, President of the Royal College of Physicians of London, Sir Patrick Manson, medical adviser to the Colonial Office, Sir William Church, Sir John Glover, chairman of Lloyd's, Mr. Jonathan Hutchinson, Mr. Watson Cheyne, Professor Howard Marsh, Major Ronald Ross, Professor W. J. R. Simpson, and Professor Augustus Waller.

After the usual loyal toasts, Mr. **CHAMBERLAIN** proposed "The London School of Tropical Medicine" and said that when he was invited to preside at this dinner he could not resist the temptation to repeat the experience of six years ago when he presided at a similar banquet at the establishment of the London School of Tropical Medicine. Now he came back to rejoice in their past success and to inquire into their future, his interest in tropical medicine being unexhausted and unbounded. He regarded it as a privilege as well as a duty to be in any way associated with the school, a privilege because he could not think of any subject of scientific research and philanthropic enterprise which was more interesting, while it was a duty which we owed to the empire and from which we could not divest ourselves whatever our political opinions might be to see that all our possessions were rendered as healthy as possible. This duty had increased in recent years with the extension of our territory, with the increase of scientific knowledge, and with the awakening of our imperial conscience. We owed this duty to the vast population for which we had made ourselves responsible and owed it also to those of our own race who were daily risking health and life in order to uphold the honour and the interests of this country. Where the British flag was planted there must be established the British prosperity; we were unable, therefore, to stay where we began. Let them compare the position of Egypt as it was a quarter of a century ago with the Egypt of Lord Cromer and note the perhaps even more extraordinary advance in the condition of the Soudan and Nigeria. These miracles had been wrought by a handful of men, mostly very young, brought suddenly into the presence of great responsibilities, having to deal with crises of administration, of disease, of savage aggression, and with every problem of statesmanship. Science had given its martyrs recently in the persons of Myers and of Dutton, and owing to our ignorance of the conditions which had to be faced or our inability to deal with them many others had left their health or their lives behind them in tropical climes. Our first duty was to do all in our power to reduce to the uttermost this blood tribute which we paid to the empire. To Sir Patrick Manson we owed the idea of a London tropical school and almost abreast of him came the promoters of the Liverpool School of Tropical Medicine They in London felt no jealousy of the Liverpool school since there was room for all in that work but they did envy them the liberality and energy of their citizens who raised something like £40 000 by private subscription Why could not London, the metropolis of the empire, the metropolis of the world of commerce emulate more frequently the generosity of a provincial city? Mr Chamberlain then referred to the work done by the London school and to the number of its students and appealed for the sum of £100 000 to repay the debt to make proper provision for the teaching and above all, to subsidise research in tropical diseases of every kind

Sir PATRICK MANSON having replied to the toast the COLONIAL SECRETARY proposed 'The Empire in an excellent speech Mr Lyttelton's words were eloquent and lofty and showed him to be inspired by a very true and far reaching patriotism though as was natural, much of what he said centred round the work of the chairman his predecessor in office

Lord STRATHCONA was the representative public man selected to reply to the toast of The Empire '

The Duke of MARLBOROUGH then gave 'The Health of the Chairman, to which Mr CHAMBERLAIN replied

Subscriptions and donations amounting to over £10 000 were received during the evening

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 12, 1827

Every variety of nervous affection does occur without any organic disease But when people have epilepsy without organic disease they generally recover or may recover If the irritation which occasioned the epilepsy continues for a length of time naturally enough, faulty vascular actions will be induced so that in people who have been long subject to epileptic fits you generally find tubercles But the subject is a most momentous and important one, and very much deserving of your attention For my own part I shall affirm that every kind of nervous malady may occur in the brain, as *functional* disorder and not as *organic* disease This is most important, because it leads to the consideration of *madness*, and why should they bleed and purge and the devil knows what poor people who are afflicted with madness as if they have all a disease of the organ the brain itself? Now here I quote Morgagni he has got a long list of diseases that he has published where tubercles were found and among that list are cases of persons who were mad from too hard a brain, from too soft a brain from a fungus in the brain, from a plexus occurring in the brain, and so on, but here comes the epigram the concluding sentence, 'but all these morbid appearances have I seen without any appearance of tubercles at all and I have seen tubercles where there have been no such morbid appearances ' There's a body of evidence for you (Much laughter) Madness is no cause of these tubercles at all I say the object we should bind our attention to is to settle nervous inquietude, to tranquilise the vital actions of the cerebrum, to cut off any cause of irritation affecting it, and I take the putting into order the *digestive organs* to be one gr d point towards accomplishing this end
what I think is the c u e c
human race, it is their
stimulating those organs to an excess thereby producing nervous disorder and irritation The state of their minds is another grand cause the fidgetting and discontenting yourselves about that which can't be helped, passions of all kinds—malignant passions
the mind disturb the cerebi
harm There is something
you are to quiet the mind
and not to keep bleeding and blistering, as if you were to cure all the diseased structure by such measures Of course preventing too powerful an impulse of the blood is important but everything is to be conducted in moderation [1]

---

[1] Excerpt from Mr Abernethy's "Physiological Pathological and Surgical Observations, delivered in the Anatomical Course of Lectures at St Bartholomew's Hospital"

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of this College was held on May 2nd, Dr J PLAYFAIR the President, being in the chair

The PRESIDENT made feeling reference to the loss which the College had sustained by the death of Sir John Sibbald

On a ballot the following candidates were admitted to the Membership of the College *after examination* Hugh Jamieson M B, C M Edinburgh, Leo Ferdinando Bianchi, L R C P L R C S Edin, L F P S Glasg, Edinburgh, Patrick Stevenson Haldane, M B Ch B Bridge of Allan, and Jamshijd Dadabhai Munsiff L R C P, L R C S Edin, L F P S Glasg Edinburgh

The REGISTRAR reported that since the last quarterly meeting 38 persons had obtained the Licence of the College by examination

The CURATOR submitted his report for the last year regarding the research and reporting work undertaken in the laboratory during the year and the expenditure incurred The report showed that 34 workers had been engaged in research, that 2426 specimens had been reported on being an increase of 61 on the number for the previous year, and that the expenditure had amounted to £1086 12*s* 4*d* The report was adopted by the College

The Parkin prize which is in the gift of the College, was awarded after competition to Dr Charles Porter The subject of the essay on the present occasion was, in terms of the deed of bequest 'On the Curative Effects of Carbonic Acid Gas or Other Forms of Carbon in Cholera, for Different Forms of Fever and other Diseases '

The TREASURER reported that the council had resolved to offer the Parkin prize for competition for the ensuing year, the subject to be in terms of the bequest On the Effects of Volcanic Action in the Production of Epidemic Diseases in the Animal and in the Vegetable Creation and in the Production of Hurricanes and Abnormal Atmospherical Vicissitudes essays to be received by the secretary up to Dec 31st 1906

Dr Norman Walker was elected as representative of the College on the conjoint committee of management of the triple qualification

It was intimated that Dr W Ford Robertson had been appointed Hon on lecturer for the ensuing session

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9533 births and 4621 deaths were registered during the week ending May 6th The annual rate of mortality in these towns, which had been 16 6 15 6 and 16 5 per 1000 in the three preceding weeks declined again to 15 4 per 1000 last week In London the death rate was 14 5 per 1000, while it averaged 15 8 per 1000 in the 75 other large towns The lowest death rates in these towns were 6 0 in Burton-on Trent 6 2 in Hornsey, 8 4 in Handsworth (Staffs) 9 6 in Leyton in Aston Manor and in Rotherham, and 9 9 in Grimsby the highest rates were 21 3 in Rhondda 21 8 in Sunderland 22 4 in Bootle, 24 0 in Merthyr Tydfil 24 2 in Smethwick 24 9 in Middlesbrough, and 26 8 in Oldham The 4621 deaths in these towns last week included 469 which were referred to the principal infectious diseases against 553 453 and 460 in the three preceding weeks, of these 469 deaths 186 resulted from measles 132 from whooping cough 47 from diphtheria, 47 from diarrhœa 29 from scarlet fever 24 from fever ' (principally enteric) and four from small pox In Hornsey, Wolverhampton Walsall Leicester Huddersfield Hull Swansea and five other smaller towns no death from any of the principal infectious diseases was registered last week, while the highest death rates from these diseases were recorded in Hanley, West Bromwich Smethwick, Coventry, Oldham Sheffield and Merthyr Tydfil The greatest proportional mortality from measles occurred in West Bromwich Smethwick Coventry Warrington Oldham, Sheffield, and Merthyr Tydfil, from scarlet fever in Wigan Burnley, and Blackburn, from diphtheria in East Ham, and from whooping cough in West Ham Leyton, Hanley Smethwick, Preston, Halifax, and South Shields. The mortality from "fever" and from diarrhœa showed no marked excess in any of the large towns. Of the four fatal cases of small-pox registered last week one belonged to London, one to Nottingham, one to Oldham, and one to Bradford. The number of small-pox patients remaining under treatment in the Metropolitan Asylums Hospitals, which had been 15, 17, and 16 at the end of the three preceding weeks, had risen again to 17 at the end of last week; four new cases were admitted during the week against none, six, and four in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2152, against 2133, 2128, and 2182 at the end of the three preceding weeks; 235 new cases were admitted during the week, against 290, 253, and 255 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 304, 272, and 306 in the three preceding weeks, declined to 256 last week, but were 63 above the number in the corresponding period of last year. The causes of 48, or 1·0 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Salford, Leeds, Hull, Newcastle-on-Tyne, and in 51 other smaller towns; the largest proportions of uncertified deaths were registered in Hanley, Leicester, Liverpool, Bootle, Blackburn, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·0, 17·8, and 18·8 per 1000 in the three preceding weeks, declined again to 18·0 per 1000 during the week ending May 6th, but was 2·6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Leith and 15·8 in Paisley to 18·9 in Glasgow and 21·3 in Perth. The 603 deaths registered in these eight towns last week included 26 which were referred to whooping-cough, 16 to measles, 15 to diarrhœa, four to diphtheria, three to scarlet fever, and three to "fever." In all, 67 deaths resulted from these principal infectious diseases last week, against 69, 69, and 59 in the three preceding weeks. These 67 deaths were equal to an annual rate of 2·0 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 36, 23, and 27 in the three preceding weeks, declined last week to 26, of which 16 were registered in Glasgow, three in Dundee, two in Edinburgh, two in Aberdeen, and two in Paisley. The deaths from measles, which had been 17, 23, and 21 in the three preceding weeks, rose to 26 last week, and included 16 in Glasgow, three in Dundee, two in Edinburgh, two in Aberdeen, and two in Paisley. The fatal cases of diarrhœa, which had been nine, 12, and eight in the three preceding weeks, rose again last week to 15, of which five occurred in Glasgow, three in Dundee, three in Leith, and two in Aberdeen. The deaths from diphtheria, which had been six, six, and one in the three preceding weeks, increased again to four last week, and included two in Glasgow. The three fatal cases of "fever," including one of typhus, were all registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 121, 126, and 121 in the three preceding weeks, rose again to 132 last week, and were 32 in excess of the number in the corresponding period of last year. The causes of 22, or nearly 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·6, 23·4, and 21·9 per 1000 in the three preceding weeks, rose to 22·0 per 1000 during the week ending May 6th. During the past four weeks the death-rate has averaged 22·2 per 1000, the rates during the same period being 15·4 in London and 17·1 in Edinburgh. The 160 deaths of persons belonging to Dublin was one in excess of the number in the preceding week and included eight which were referred to the principal infectious diseases, against eight, 12, and eight in the three preceding weeks; of these, three resulted from measles, three from "fever," one from whooping-cough, and one from diarrhœa, but not any from small-pox, scarlet fever, or diphtheria. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·5 in London and 0·9 in Edinburgh. The fatal cases of measles, which had been four, four, and two in the three preceding weeks, rose last week to three. The three deaths from "fever" were slightly above the number in the preceding week. The 160 deaths in Dublin last week included 28 of children under one year of age and 44 of persons aged 60 years and upwards; the deaths of infants were slightly in excess of the number in the preceding week, while those of elderly persons showed a decline. Two inquest cases and two deaths from violence were registered; and 61, or nearly 40 per cent., of the deaths occurred in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·6 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 5·8, 5·9, and 6·0 per 1000 respectively. The lowest rates last quarter were recorded in Kensington, City of Westminster, Islington, the City of London, Southwark, and Battersea; while the highest rates occurred in Bethnal Green, Stepney, Poplar, Wandsworth, Lewisham, and Woolwich. Small-pox was rather less prevalent than it had been during the preceding month; the 15 cases notified during April included six in Lewisham, two in Paddington, and two in Woolwich. The Metropolitan Asylums hospitals contained 16 small-pox patients at the end of last month, against 15, 15, and 20 at the end of the three preceding months; the weekly admissions averaged four, against one, three, and four in the three preceding months. The prevalence of scarlet fever during the month under notice showed a very slight decline from that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Hackney, Stepney, Wandsworth, Camberwell, Deptford, Lewisham, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 2067, 1941, and 1997 at the end of the three preceding months, had further risen to 2152 at the end of last month; the weekly admissions averaged 266, against 209, 231, and 272 in the three preceding months. The prevalence of diphtheria showed a considerable decrease compared with that in the preceding month; the greatest proportional prevalence of this disease occurred in Hammersmith, Fulham, Shoreditch, Bethnal Green, Stepney, Poplar, and Woolwich. The Metropolitan Asylums hospitals contained 719 diphtheria patients at the end of last month, against 836, 837, and 788 at the end of the three preceding months; the weekly admissions averaged 83, against 115, 118, and 98 in the three preceding months. Enteric fever was slightly less prevalent than it had been in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Chelsea, Holborn, Poplar, Southwark, Deptford, and Woolwich. The number of enteric fever patients remaining under treatment in the Metropolitan Asylums hospitals at the end of last month was 65, against 134, 105, and 68 at the end of the three preceding months; the weekly admissions averaged 11, against 17, 13, and 11 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Shoreditch, Bethnal Green, Stepney, and Poplar. The 19 cases of puerperal fever notified during the month included three in Lewisham and two each in Islington, Hackney, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending April 29th the deaths of 5422 persons belonging to London were registered, equal to an annual rate of 15·1 per 1000; in the three preceding months the rates had been 17·0, 16·4, and 15·5 per 1000. The rates

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1905

* Including membranous croup

last month ranged from 10·4 in Hampstead, 11·3 in Stoke Newington and in Greenwich, 12·0 in Wandsworth, 12·1 in the City of Westminster, and 12·8 in Lewisham, to 17·9 in Bermondsey, 18·6 in Poplar, 19·6 in Finsbury and in Bethnal Green, 20·9 in the City of London, and 21·7 in Shoreditch. The 5422 deaths from all causes in London last month included 516 which were referred to the principal infectious diseases; of these, two resulted from small-pox, 166 from measles, 45 from scarlet fever, 45 from diphtheria, 192 from whooping-cough, 18 from enteric fever, and 48 from diarrhœa. The lowest death-rates from these diseases were recorded in the City of Westminster, Stoke Newington, the City of London, Lambeth, Deptford, and Lewisham; and the highest rates in Fulham, Shoreditch, Stepney, Poplar, and Battersea. Of the two fatal cases of small-pox one belonged to Hackney and one to Lewisham. The 166 deaths from measles were 110 fewer than the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Stoke Newington, Finsbury, Shoreditch, Poplar, Bermondsey, and Battersea. The 45 deaths from scarlet fever were six in excess of the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in St. Marylebone, Holborn, Shoreditch, Poplar, Wandsworth, and Woolwich. The 45 fatal cases of diphtheria showed a decline of 62 from the corrected average; among the various metropolitan boroughs diphtheria was proportionally most fatal in St. Pancras, Finsbury, Shoreditch, Bethnal Green, Stepney, Greenwich, and Woolwich. The 192 fatal cases of whooping-cough were 45 below the average number in the corresponding periods of the ten preceding years; this disease showed the greatest proportional mortality in Paddington, Hammersmith, Fulham, Hackney, Shoreditch, Stepney, Southwark, and Wandsworth. The 18 deaths from "fever" were seven fewer than the average, and included two in Paddington, two in Hampstead, two in Hackney, two in Poplar, and two in Lewisham. The 48 fatal cases of diarrhœa showed a slight decline from the corrected average number; among the various metropolitan boroughs the highest death-rates from this disease were recorded in St. Marylebone, Shoreditch, Poplar, Southwark, Camberwell, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 31 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 115 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Stoke Newington, Holborn, the City of London, and Woolwich; and the highest rates in Kensington, Hammersmith, Shoreditch, Stepney, Poplar, and Deptford.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Robert Forbes Bowie has been placed on the retired list, at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated May 7th, 1905).

The following appointment is notified:—Surgeon G. E. Glynn to the *Excellent* for the *Grafton.*

ROYAL ARMY MEDICAL CORPS.

Lieutenant D. S. B. Thomson is seconded for service with the Egyptian Army (dated April 21st, 1905).

—The undermentioned Captains to be Majors (dated April 29th, 1905):—H. C. French, E. M. Williams, and J. R. McMunn. The undermentioned Lieutenants are confirmed in that rank:—L. V. Thurston, A. W. Gater, and J. P. Lynch.

IMPERIAL YEOMANRY.

Essex: Charles Gordon Roberts (late Second Lieutenant) to be Surgeon-Lieutenant (dated May 3rd, 1905). East Riding of Yorkshire: Surgeon-Lieutenant R. H. Ashwin resigns his commission (dated May 3rd, 1905).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Forfarshire: Surgeon-Lieutenant J. Gray resigns his commission (dated May 3rd, 1905).

Rifle: 2nd Tower Hamlets: Herbert Samuel Stockton to be Surgeon-Lieutenant (dated April 10th, 1905). 2nd Volunteer Battalion the Hampshire Regiment: Surgeon-Captain O. T. Stephenson resigns his commission (dated May 10th, 1905). 2nd Volunteer Battalion, the Manchester Regiment: Surgeon-Lieutenant J. A. K. Renshaw to be Surgeon-Captain (dated May 10th, 1905). 1st Volunteer Battalion the Royal Warwickshire Regiment: Wilfrid Allport to be Surgeon-Lieutenant (dated May 3rd, 1905). 1st Volunteer Battalion the Norfolk Regiment: Supernumerary Surgeon-Lieutenant J. M. G. Bremner to be Surgeon-Captain and to remain Supernumerary (dated May 3rd, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Manchester Companies: Lieutenant G. Fyfe Waterston resigns his commission (dated May 10th, 1905).

RECRUITING IN MANCHESTER.

In the year ending Sept. 30th, 1904, 5038 men offered themselves for enlistment in Manchester. Of these 1962 were at once rejected, while of those passed on for the medical examination 1522 failed to pass. 1378 were finally approved, so that about 69 per cent. were rejected "as unfit for military training and service." Much the same experience has been passed through at other recruiting centres in Lancashire. It is, therefore, very naturally stated that "the steady increase of physical infirmity amongst the class to which the army looks for its recruits provides ground for much anxious thought." Enlistment is not now popular, so that the recruits come largely from those who have difficulty in obtaining work, to whom it is an alternative preferable to starvation. The standard of height has been gradually lowered. In 1870 and immediately following the introduction of the short-service system the height of the infantryman was to be 5 feet 8 inches. In July of the same year the standard was lowered 2 inches to 5 feet 6 inches and in September to 5 feet 5½ inches. In 1871 it was dropped again to 5 feet 5 inches and in 1873 to 5 feet 4½ inches. In 1884 it fell to 5 feet 4 inches and to-day it is 5 feet 3 inches, while during the war in South Africa we were so short of men that little fellows of "only 5 feet" high were accepted. More serious than the deficient number of inches, on account of which indeed, only a small proportion were rejected, is the fact that many failed on account of "small chest measurement." The majority, however, were passed over because of bad teeth and "flat feet,' while many had defective eyesight. It is said that thousands are turned away for flat feet, which is considered by some to be due to the wearing of clogs. There can be no question that among the class from which these would-be recruits come, the "ne'er-do-wells" and "out-of-works," who, thanks to the short-service system go in for "a spell of soldiering," there is grievous deterioration of physique, but it does not follow that it runs through the whole social scale. Their numbers are, however, so great that this decadence is a serious danger to the future of the nation. There are many and diverse ideas afloat as to the best means of remedying the evil, from the feeding of underfed children, without apparently much care about the removal of responsibility from the parents, to the scheme of universal military training advocated by the National Service League. There is little doubt that the latter, if the people and the Government would have it carried out, would do much not only for the physique but the morale of the younger generation, quite apart from any question of the defence of our shores.

THE WAR IN THE FAR EAST.

Notwithstanding the feeling of tension and anxious expectation with which the political world has of late been watching the course of events in regard to the presence of the Russian fleet in territorial waters in the Far East and the steps which were being taken by the French Government to insure the observance of neutrality, there has been a dearth of news, and especially of a medical nature, from the actual seat of war. At the present time the position may be succinctly summed up as follows. Admiral Rojdestvensky's fleet, which had been the cause of this grave difficulty, has left the Bay of Vanfong for some unknown destination. Admiral Togo's fleet has disappeared and its position is still a well-maintained secret, and with respect to the land forces we have of late heard little or nothing about Marshal Oyama's movements. As regards medical news, we learn from St. Petersburg that, according to the *Novoye Vremya*, there is in the region between Lake Baikal and Vladivostock a total of over 2000 sick and wounded Russian officers and 30,368 men.

AN INTERESTING NOTE UPON HOLDEN'S OSTEOLOGY.

To the Editors of THE LANCET.

SIRS,—I have only very recently read your obituary notice of my old teacher and friend, Luther Holden. It has much interested me. Referring to his great and admirable work, "Human Osteology," you say, "When it appeared (viz., in 1855) the reviews generally contained the remark, 'Why did no one think of this before?'" A most natural question, seeing how simple a matter it was. In connexion with it, however, there are a few facts relating to what preceded which may have an interest as illustrating the manner in which the practical applications of inventions often come about.

From 1846 to 1850 I was a student at St. Bartholomew's Hospital. During the winter session of 1848–49, with the view of acquiring for myself a more accurate knowledge of the attachments of muscle, I brought to the dissecting room the bones of the portion I was dissecting and carefully drew with a pencil the outline of the space occupied by the attachment of each muscle. When I had satisfied myself as far as possible of the correctness of these outlines I took the bone home and painted with Indian ink the whole surface included in the outline of each muscular attachment. When a bone was thus completed it was varnished. At this time Mr. Holmes Coote and Mr. Luther Holden were our demonstrators in the dissecting room. I passed the examination of the College of Surgeons shortly before Christmas, 1849, and that of the Apothecaries' Company in May, 1850. Before I left the hospital Mr. Coote asked me to lend him my marked bones. I did so with alacrity, feeling gratified that he took an interest in them, and he kept them many months. Shortly after he had returned them his little book on the bones was published with illustrations, on which were shown for the first time in fine outlines the attachments of the muscles. Not long afterwards Mr. Coote died. One day I had some of the bones in the museum when Sir William Lawrence was there. On [illegible] t them attentively, then [illegible] l his lips, as his manner [illegible]

[illegible] r offered me a tempting opening in the old concern in Plough-court, Lombard-street, and being engaged and anxious to marry I gladly accepted it, and, abandoning all idea of practice, soon became closely occupied with other interests, and it was, I believe, some years after the publication of Mr. Holden's beautiful book that I first saw it. I had intended to let the above particulars die with me but the reviewer's remark quoted by you, "Why did no one think of this before?" seems to invite the foregoing statement.

I am, Sirs, yours faithfully,

Little Berkhamsted, May 9th, 1905. CORNELIUS HANBURY.

PS.—I am sending the bones I marked to the museum of St. Bartholomew's Hospital, where, no doubt, they will be open to the examination of anyone interested and may afford a useful suggestion to some careful students.

THE TREATMENT OF TUBERCULOSIS OF THE LUNGS BY MEANS OF TUBERCULIN.

To the Editors of THE LANCET.

SIRS,—In my article on the Treatment of Tuberculosis of the Lungs by Means of Tuberculin and other Bacterial Derivatives, published in THE LANCET of April 8th last (p. 923), I made the following statement in criticism of the results obtained by Dr. Lawrason Brown in the treatment of pulmonary tuberculosis by means of tuberculin: "And criticising the figures given by Brown it would really appear that 204 out of 282 cases were apparently cured without tuberculin, which is 72·3 per cent.—*greater* than the results with tuberculin."

Dr. Lawrason Brown has pointed out that this is a mistake on my part and that instead of 204 the figures should be 173. This would give a percentage cure without tuberculin of 61·3 per cent. and Dr. Lawrason Brown has pointed out in his admirable article in the *Zeitschrift fur Tuberkulose und Heilstattenwesen*, 1904, Band vi., Heft 4, S. 235, that he has been able to secure an apparent cure in similar cases, using tuberculin, of 72 per cent., which is 10·7 per cent. better than when tuberculin was not used. I am the more wishful to correct this mistake, for Dr. Lawrason Brown has taken the greatest care to avoid making extravagant claims in favour of tuberculin. Dr. Lawrason Brown's results support the favourable reports published by others on the value of tuberculin in suitable cases and do not militate against them, as my remarks may have led your readers to think.

I am, Sirs, yours faithfully,

May 8th, 1905. H. BATTY SHAW.

IF TUBERCULOSIS SHOULD BE CERTIFIED, WHY NOT SYPHILIS?

To the Editors of THE LANCET.

SIRS,—In the correspondence on this subject in THE LANCET one point appears to have escaped notice—viz., that before notifying a disease it is necessary to diagnose it. In the evidence before the recent committee on physical deterioration Sir Alfred Cooper stated: "It is advisable that there should be special departments at general hospitals for the treatment of this class of disease and all such cases should be relegated to that department. It should be under the charge of someone specially skilled in that branch of professional knowledge and a course of instruction in that subject should be compulsory for every student. These special departments have been in existence for years past in the majority of European countries and in America." In fact, in this country there is no systematic teaching of syphilis and venereal diseases and the majority of medical men go into practice knowing little or nothing of two of the most widespread and disastrous diseases which afflict mankind. Until this state of affairs is altered it is idle to speak of notification.

I am, Sirs, yours faithfully,

May 4th, 1905. C. F. MARSHALL, F.R.C.S. Eng.

THE RELATIONSHIP BETWEEN PLAGUE-INFECTED ANIMALS AND THE DISEASE IN MAN.

To the Editors of THE LANCET.

SIRS,—In dealing with Professor W. J. R. Simpson's "Treatise on Plague" in THE LANCET of May 6th, p. 1205, your reviewer attributes certain experiments carried out in Natal on the "relationship between plague-infected animals and the disease in man" to Mr. Ernest Hill. May I be permitted to point out that this is not quite correct? A full account of the experiments in question is embodied, it is true, in Mr. Hill's "Report on the Plague in Natal," 1902–03, but practically the whole of the work was carried out by Mr. H. Watkins Pitchford, the Natal Government bacteriologist, and Dr. Haydon.

I am, Sirs, yours faithfully,

H. S. WILLSON, M.B. Cantab.

King's College, Strand, W.C., May 9th, 1905.

THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

Committee Meeting at Berne.

(From a Special Correspondent.)

(Concluded from p. 1232.)

Berne, May 1st.

On the reassembling of the committee in the afternoon, Dr. **Posner**, from the chair, opened a discussion on the means of drawing the affiliated associations closer together and rendering the international organisation of real service to the public and to its members. He thought that the publication of an "Annual" might help if it supplied the members with a list of the journals belonging to the International Association, with the rules governing the national associations, and with accounts of the meetings that had been held and of the measures taken. It would be something to show, some testimony and proof that useful work had been done. Such a publication should be issued in time for the Lisbon Congress and if not brought out every year it should at least appear before every great international medical congress.

Dr. **Blondel** and Dr. **Bossi** thought that such a publication would make others more anxious to join the association and the principle that such an "Annual" should be issued was adopted.

Dr. **Péchère** then suggested that journals on their title page should mention the fact of their affiliation to the International Association.

Dr. **Jaquet** inquired how it was proposed to separate the genuine medical press from publications that were issued by manufacturers merely to advertise their drugs, instruments, &c. The latter were often mistaken for *bonâ fide* scientific publications. The proclamation of affiliation should have a moral and scientific effect, it should constitute a privilege, but it was necessary to see that it was worthily employed.

Mr. **Adolphe Smith** said that he gathered that before anything of the sort could be done a considerable work of purification had to be accomplished by some national associations. Before the Conference of Monaco and the publication of the rules there proposed an undesirable element had gained admission.

Dr. **Péchère** thought that the work of purification had been accomplished.

Dr. **Bombarda** said that certainly this was the case in Portugal.

Mr. **Adolphe Smith**, in answer to questions, said that in England the difficulty as yet was not how to expel unworthy members but how to find a sufficient reason to prevent such from joining.

Dr. **Blondel** explained that at first in forming an International Association it was necessary to accept what existed. An international association that existed only as a project could not dictate to national associations that had been in practical life for several years. Now, however, they might begin to register members and where a national organisation had members whose qualifications did not correspond with the Monaco rule the fact should be mentioned.

Dr. **Doléris** promised that the work of purification would be undertaken in France. Many applicants for membership of the French Association of the Medical Press had been rejected. Of late, however, a leakage had occurred.

Dr. **Larra** explained that the Spanish Association of the Medical Press had been in existence for 23 years. It was not possible to exclude journals of 23 years' standing. Fortunately, these were all honourable publications, but the rules differed, inasmuch as the organs of allied professions, of chemistry, and of the veterinary surgeons had been admitted.

Dr. **Blondel** was very anxious to know who was going to undertake the work of purification. Was it the executive of each national association? He thought that some of them would fear to act and, moreover, did they as a central authority possess the power? On paper, at least, it seemed to exist in the second paragraph of Article XI of Chapter II.

Dr. **Péchère** considered such power excessive.

Dr. **Bombarda** said that the committee could not go beyond the national societies or interfere with them. Each nationality must do its own work of purification. Besides, a journal might be very honourable to-day and might degenerate to-morrow. An international committee could not watch such fluctuations and be responsible for all the nations.

Mr. **Adolphe Smith** also insisted on leaving the greatest possible autonomy to each nation. Each national association must bear the sole responsibility of the selection which it made.

Dr. **Blondel**, however, thought that the Berne Conference had the right and the duty to call upon the national organisations to endeavour to carry out the general principles as to membership and to supply full information as to the measures which they were taking to that effect. Dr. Blondel, as general secretary of the International Association, moved:—

> That the present meeting of delegates, so as to conform with the rules, should authorise him to write to the general secretaries and ask them for a list of proposals or rules of their respective National Associations which relate to the journals that they desire should be affiliated to the International Association, at the same time pointing out to them that the assembly of delegates united at Berne expressed the desire that the National Associations should only propose such journals as were exclusively scientific publications and excluding publications distributed gratuitously.

This was adopted unanimously.

Several speakers thought that the power of the International Association would be greatly increased if one or two important questions on which all parties agreed were simultaneously discussed in the journals of all the nationalities represented. The presence of wealthy patients, who could afford to be treated at home, in the beds of hospitals intended for the poor was an example of the sort of question—a grievance which existed in all countries and about which joint international pressure could be brought to bear. This suggestion was very generally approved and perhaps some such subject will be submitted next year at Lisbon. It was also urged that the card of membership would be of use if all members made it a matter of duty to honour and to assist those who bore this card, especially when travelling. This was agreed to and the card will shortly be issued. But it must be borne in mind that to be a member of the International Association the candidate must notify the international general secretary, Dr. Blondel, that he approves the rules, and this must be accompanied by a certificate from the president of his own national association to the effect that he is a fit and proper person. It will be for the presidents of national associations, where the work of purification is going forward, to be careful how they endorse applications made to the international general secretary. The latter will issue cards of membership only in response to the signature of the president of a national association of the medical press.

The very practical question concerning the work to be done at Lisbon next year then came up for discussion. The first point to decide was whether there should be at Lisbon an open congress such as had been held in Paris and Madrid, at which the entire medical press of the world would be invited to attend, whether belonging or not to the International Association. On the one hand such a course has the advantage of drawing together a large number of persons and it provides an opportunity of recruiting new members for the association. Moreover the authorities are more ready to take note of a large congress and to pay some sort of compliment to its members. On the other hand, such congresses can only express pious wishes, for the International Association of the Medical Press cannot allow itself to be governed by resolutions adopted at a congress where a great part of the members present do not belong to the association. The association may have something, perhaps even a great deal, to learn from expressions of opinion gathered from outside but its policy can only be determined by the majority within its own ranks. Therefore when a congress is held it is necessary to have at the same time a meeting of members and it is not easy to manage both together. This difficulty was felt keenly at Madrid, where the better part of two days was spent in the magnificent hall of the Central University listening to fine speeches delivered by irresponsible persons, and when, meeting later in a small side room, the members of the association wanted to attend to their practical work no sufficient time remained for this purpose. Yet there are occasions when the noise and publicity of a large congress may be of use, but such use is more local than international. Indeed, a congress is generally a means of stimulating and of educating local opinion, of creating or of reviving interest in the questions discussed. Therefore it should be left to the Association of the Medical Press where the meeting was to take place to decide whether this should be a general meeting of the International Association or a congress with its doors open to all comers. A proposal to this effect made by the British delegate was at once adopted by the committee. Dr. **BOMBARDA** then explained that his hands were so full with the organisation of the Fifteenth International Congress of Medicine that he feared he could not undertake to organise yet another such assembly. After a good deal of conversation it was agreed that there should be no congress of the medical press but that a general assembly of the entire International Association of the Medical Press should meet on Tuesday and Wednesday, April 17th and 18th, 1906, at Lisbon; that is on the two days previous to the day fixed for the opening of the Fifteenth International Congress of Medicine. No one will be admitted who is not a member of the International Association of the Medical Press, but as all who are members can attend there will be no question of sending delegates. The vote will then be by nationality according to Article XII. of Chapter III. of the rules. The Portuguese Association of the Medical Press will make arrangements to provide a room for the meetings and will probably be able to print a report of the proceedings. Nothing more is offered, but, on the other hand, no entrance fee will be charged. Dr. **BOMBARDA** [illegible] all who will attend the meetir[illegible] also be attending the Medical C[illegible]plify matters to avoid having t[illegible]way tickets, &c. All the advantages and hospitality offered would come to them as members of the Medical Congress.

Dr. **PÉCHÈRE** and Dr. **BLONDEL** thought that the Medical Congress should offer some special recognition or privilege to the International Association of the Medical Press. For instance, 18 cards of honorary membership might be given to the 18 members of the Committee of the International Association of the Medical Press.

The subjects to be put down on the agenda for the Lisbon meeting were next considered. The first question inscribed, with Dr. Blondel and Dr. Posner as reporters, relates to publishing a brief summary of the original articles for purposes of ready reference. They will also report on the advisability of issuing a bulletin. From France a third subject will be introduced—namely, the adoption of the title of "Doctor" for the purpose of signing articles or even advertisements when the writer is not a medical man. Dr. Bossi wants to discuss the relations of medical practitioners with the political press and Mr. A. Smith proposes that Portugal should be allowed two representatives instead of one on the International Committee. Of course many more questions will be introduced for debate before the date of the meeting at Lisbon.

A somewhat animated discussion followed in regard to the work of the press at the Lisbon Congress of Medicine. How could the organisers of the Congress help the press and how could the press be of use to the Congress?

Dr. **BOMBARDA** said that the faults committed at Madrid had been carefully noted, that the very best intentions prevailed at Lisbon, and that full confidence might be placed in the organisers. There was some difficulty in explaining, in making it quite clear, that every confidence existed as to the good intentions of the organisers of the Lisbon Congress of Medicine. At the same time the organisers could not be expected to know what were the requirements of the press unless they were told. Instead of every individual journalist sending in his own personal request or complaint the International Association of the Medical Press had been formed to present once and for all such requests or such complaints, and this in an authoritative manner as the desire or criticism not of one journalist or of one paper but of many papers belonging to many nations. Such collective representations would save much time and would facilitate the work of the organisers of medical congresses. To-day at Berne a committee of technicians were gathered together competent to enter into minute details of what was necessary, so that the work of the press, on which the success of the congress in the main depended, could be best accomplished. For instance, a room where members of the press could work quietly was very necessary. At Madrid such a room was provided but was invaded by a constant flow of distributors of advertisements and touters. Dr. Bombarda promised to do as much as the geographical conditions rendered possible. They were endeavouring not to scatter the Congress of Medicine but to hold it under one roof. This would be that of the new medical schools which were now being built. But the congress had already 20 sections and the number was increasing. Then they had 13 separate offices, a lounge, a ladies' saloon, &c. The committee protested that the work of the press was of more importance than a saloon for ladies, particularly as the crush room of the principal theatre had been set aside for their use during the congress week. It was decided that the members of the press should have a special card over and above the ordinary card of members of the Congress of Medicine and that a special room should be placed at their service and a doorkeeper appointed who would not allow anyone to enter unless he showed the press card. This would be done even at the sacrifice of a subsection if necessary. But it was difficult to say how large this room would be—first, because there was but limited space; and secondly, because it was difficult to ascertain how many working journalists would be present. It had been said, but it was not possible to discover on what authority, that there were 70 journalists at Madrid and 80 at Rome. The next point was with regard to letters. There would be a post installed at the congress, but pressmen had too much work to do to wait in the midst of a large crowd for their letters. Letters headed "Press Bureau" or "Press Service" should be put into separate and special alphabetically marked pigeonholes and conveyed either to the press room or served out by a special attendant at a different part of the counter.

In regard to the reporting of the proceedings in the sections there will be in each section a table set apart for the press. Further, the secretaries of the sections will be requested to remain in the room for a little while after their section has adjourned. They will then read out slowly to the pressmen gathered round them the summaries of the speeches which each person who takes part in the discussion is at once requested to write. Those members of the Congress who are to propose motions will be requested to bring several copies of the same with them for distribution to the press. Efforts also will be made to establish on the spot an office where writers of papers or speeches can go and have copies of the same promptly printed at their own expense. This was done with great effect in Paris in 1900 and was of service to the authors and to the press. It was also suggested that medical students speaking other languages than Portuguese should be invited to attend and to help as interpreters. Then the request was made that a representative of the International Association of the Medical Press should be allowed to speak at the inaugural meeting. Dr. Bombarda promised that he would endeavour to make the necessary arrangement. The press is a Power and as such should speak with the representatives of the Powers. This principle was accepted at Madrid and there was no reason why it should be set aside at Lisbon.

On the other hand, the delegates at Berne were anxious to know what on their side they could do to help the organisers of the Lisbon congress. They could always be of use in putting into circulation whatever it was desirable should be made known and each national secretary placed himself at the disposal of Dr. Bombarda to notify the press of his country whenever the need or occasion arose.

[illegible] questions. [illegible] was read [illegible]ciation of the Dutch Medical Press. The initiative had been taken by one of the best papers in Holland and the association consisted of 14 papers, three issued every month, one quarterly, and one publication which qualifies itself as "irregular."

The minutes of the previous meeting were read and confirmed and then Mr. **ADOLPHE SMITH**, as instructed by the Association of the British Medical Press, moved that:—

> Copyright of articles in a medical journal should be of such a nature as to preclude advertisers from misusing such articles or any quotations therefrom.

Dr. **BLONDEL** having remarked that he was under the impression that the French law punished all who made detrimental quotations the motion was carried unanimously.

Dr. **DOLÉRIS**, on behalf of the Association of the French Medical Press, described at length difficulties in regard to the reproduction of the medical thesis which forms part of the examination for the doctor's degree. As this question is fully explained in the motion proposed it may suffice to give the text. Dr. Doléris moved that:—

> Considering, firstly, that practically the inaugural thesis is an obligatory test accompan[illegible] the exam[illegible] and [illegible] debate. Secondly, that if this [illegible] be publ[illegible] pan[illegible]nd sold to the profit of the [illegible] much

> attenuated by the obligation of sending a considerable number of copies to the professors attached to the universities, the libraries of the faculties and of the schools of medicine; and that further the thesis of the doctorate of medicine is generally and gratuitously distributed by the author himself to a large number of members of the profession, that all this constitutes an extensive publicity which considerably reduces the commercial value of the work. Thirdly, that the reproduction in a journal of an inaugural thesis, even if it possesses a really original character instead of being a mere compilation followed by the same conclusions that are given in classical text-books, can only confer on the author professional and moral advantages that are vastly superior to the profits of the sale of the work. Fourthly, that finally [illegible] lectures, and notes has [illegible] the committee of the [illegible] express the opinion [illegible] cannot, as a rule, be considered to constitute an appreciable material damage. That, further, there can be no question of a penal offence, as the evident intention of the journalist is to render service to the author by giving him a gratuitous publicity.

The feeling on this proposition was not unanimous though it was adopted by the majority. It appears that in France no less than 280 copies have to be sent of the thesis to the various faculties. At the Berne Bureau on International Copyright the question of this form of medical thesis had never been discussed.

An important point was raised by Dr. POSNER. He said that German journals occasionally received interesting papers from foreign, notably from Italian, professors. These might be accepted and published in a German journal. Then some time afterwards it was discovered that they had already appeared in an Italian periodical. No mention of this had been made when the paper was offered and it was not always certain that the translation offered was an authorised translation or even a correct translation. Such difficulties became more acute when dealing with, for instance, the Russian or the Polish language.

Dr. BLONDEL remarked that according to the Berne International Convention on Copyright authors had no right to allow several publishers to issue the same work.

Dr. PÉCHÈRE insisted that no publisher or journal should be offered a work that was going to appear elsewhere in whatever country or language without being fully informed of the fact.

Dr. POSNER pointed out that the priority of publication was also involved and did not belong to the purchaser of a work if it could be shown that it had already appeared elsewhere, though this might be in another country and another language. He therefore proposed the following motion:—

> The Conference of Berne,—considering that some authors are in the habit of publishing their works simultaneously in several journals without informing the editors of these journals, that this custom gives rise to great difficulties for the orientation of literature and the establishment of priority in literary property, and that it is injurious to the rights of the publishers who have purchased these works,—declares that it is not admissible that an author should be able to publish the same work in different journals unless it be a translation authorised by the original publisher. The members of the association are therefore *authorised to insist that the authors who offer them an original* work shall be called upon to affirm that the work is not published or about to be published elsewhere.

The motion was carried unanimously and this concluded the labours of the Conference.

Dr. POSNER, who had occupied the chair throughout, then rose and said a few parting words. He thought that the committee had every reason to offer special thanks to Dr. Bombarda for his presence. He had come a very long way and they all hoped to see him again next year at Lisbon. His presence at Berne had been of the greatest use in view of the forthcoming International Congress of Medicine, of which he was the general secretary. He might carry home the assurance that the press was unanimous in wishing him all success in the organisation of the next medical congress. Every member of the conference assembled at Berne would do his best to promote its success.

The chairman then dissolved the meeting and the members parted company well satisfied with the interesting and practical discussions which had been held during the two days.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Infants at School.

AT the last meeting of the Lancashire county council Dr. Trimble drew attention to the large numbers of children under five years of age now in the elementary schools. They were very liable to catch infectious diseases which often proved fatal and he thought that their exclusion would be of great service from a public health point of view and would leave more room for older children, thus rendering it unnecessary to build some of the new schools which were said to be required. The chairman of the health committee, Mr. R. Sephton, said that the committee had appointed a subcommittee to discuss the subject with the education committee. From some points of view it would be desirable to exclude young infants from the schools, but though they may not assimilate much literary food they learn something of regularity of habit, of combined movements, and so forth, while their mothers would be greatly perplexed when the children were not allowed to attend the schools—those conveniently arranged day nurseries where for several hours a day they are so well looked after. This may not be the proper function for the school but it suits the parents, and in the manufacturing districts where the mothers work in the mills the infants would probably be left to the care of some old woman who might or might not attend to them properly and where the hygienic arrangements would most likely be worse than at the school. Whatever may be the case with older ones it does not appear that there is much fear of overburdening the minds of the youngest children, as few of the teachers consider them very seriously as regards tuition. As to the serious question of the epidemics in the schools there is, of course, some difference of opinion. In a letter to the *Manchester Guardian* Mr. W. Percy Bean says that in his opinion bad ventilation is the cause and that "the splendid well-built modern schools are the worst offenders," not that ventilation is ignored but because "the modern buildings are built of less porous material and also because the arrangement of class rooms is entirely against good natural ventilation." The older, more rickety buildings had the advantage as to this point but it is more than doubtful that county councils will allow of school ventilation being carried on through porous walls. He says, moreover, that on analysis of the air the same thing obtains in the "well-built, modern mill" where it is much worse than in the older ones. "This, of course, applies to those mills which are not ventilated by means of power but (depend) on doors and windows and other natural means of ventilation." He makes a very serious charge as to the "average school," which is, he says, "hundreds per cent. worse in air sewage than a cotton manufacturer would be brought before a magistrate and fined for." "A normally pure air contains about four volumes of carbon dioxide in 10,000," and a mill-owner would be fined if it were found to contain more than an additional five volumes, and he goes on to say, "I doubt if you would find in an ordinary modern class-room less than 20 to 30 volumes of carbon dioxide per 10,000 or from 400 to 600 per cent. more than a manufacturer would be fined for." He states that during the last 12 years he has made thousands of analyses of the air of schools and mills, and has "never yet found a school which could possibly compare with an average mill." He considers that the lowered vitality of the children from breathing "air sewage" increases the susceptibility to infection and that if the schools were properly ventilated the epidemics would cease. He does not think natural ventilation sufficient but that "power will have to be used." Efficient ventilation seems the most difficult problem that architects have to solve and no one will say that their success has hitherto been marked. Most certainly if these statements as to the air of our elementary schools are true the matter should be dealt with without delay.

Manchester Soot.

At the meeting of the Literary and Philosophical Society on May 2nd an interesting paper was read on the composition of the soot which Manchester produces in rare abundance. Before the paper was heard, however, Sir William H. Bailey delivered his inaugural address as president. He claimed that for original work the society was the equal of the Royal Society of London, "not ignoring the work of Sir Isaac Newton, Halley, Boyle, and other great schoolmasters of God's creation. In its ranks had been those great discoverers of the two great departments of the conservation of energy and the indestructibility of matter—Dr. Joule and Dr. Dalton." Coming after them he named William Sturgeon, "the discoverer of the soft iron electro-magnet, the 'unit invention' of electric traction and electric light, &c." Whether the Royal Society will admit the claim to equality is doubtful, or perhaps not doubtful, but the claim to distinction of Joule and Dalton is granted all the world over.

It is, however, pleasant for Manchester people to hear this cheery estimate by Sir William Bailey of the society of which they are excusably proud The paper by Professor Edmund Knecht was on Some Constituents of Manchester Soot He pointed out that smoke and soot did not consist of carbon alone, as popularly supposed, and showed that the soot from the "fat' coal used in the Manchester district contained at least 50 per cent of substances other than carbon and named the following substances which had been isolated from an average specimen of Manchester household soot snow white samples of ammonium chloride, ammonium sulphate, calcium sulphate, and a beautifully crystallised paraffin hydrocarbon, similar in properties and composition to one known to exist in bees' wax There were also 13 per cent of heavy hydrocarbon oils Professor Knecht had prepared a dye stuff which produced absolutely fast shades of brown on cotton Analysis showed that the London soot and that of Prague, especially that from Bohemian lignite, were much cleaner than Manchester soot He commented on the drawbacks attendant on the presence of soot in our atmosphere, chiefly from household fires, but did not hope for any amelioration unless the use of more efficient fire grates could be made compulsory

Purer Streams

Impure air and foul water are two evils that man is always producing and always trying to remedy at least in these days Beginning, as they did, by small degrees when the population was less dense than now, the evil was scarcely noticed but it has now assumed such proportions that it is most difficult to effect a remedy As to smoke and soot, very little has been accomplished and not much perhaps as to our rivers and streams, but still quite enough to justify Sir J T Hibbert, at the meeting of the Mersey and Irwell joint committee on May 2nd, in the cheerful view he took of the progress already made in Lancashire He said that now there was only one out of the 95 local authorities that had not provided in any way for its sewage and only five manufacturers It is encouraging to know that Manchester and Salford, whose task has been most arduous and costly, were complimented on what they had done The report of Mr R A Tatton, the chief inspector, showed that of 23 effluents recently tested only four were below the committee s standard A good deal more purification however, must be done before many once famous trout streams are restored to their former condition

Manchester Bequests

Miss Hannah Beswick of Mossley has left £1000 each to the Ashton under Lyne Infirmary the Manchester Royal Infirmary, the Manchester Eye Hospital, and Henshaw s Blind Asylum, and the residue of her estate, nearly £24 000 after certain bequests amounting to £700 or £800 to some of the local churches to be divided equally between the four institutions named above

May 8th

LEEDS

(FROM OUR OWN CORRESPONDENT)

The late Sir John Barran

BY the death of Sir John Barran Leeds has lost one of its citizens of whom it has reason to be proud and the University of Leeds has to mourn the loss of one of its first honorary graduates and one of its most loyal and consistent supporters Sir John Barron was one of those who founded the Yorkshire College which is now merged in the new university, he was a member of the council from the time that body was constituted, chairman of the finance committee from 1896, and from 1901 till his death he was treasurer Himself a generous donor to the funds of the college and university he possessed the happy power of stimulating generosity in others The relation of Sir John Barran to the city and University of Leeds was concisely and admirably expressed as follows by the Vice Chancellor Dr N Bodington, when the honorary degree of Doctor of Laws was conferred on him last October —

shire College was proposed no one stood before him in welcoming and aiding the scheme He is one of the few original members of the council of the College who are still with us and he is one without whose continual and energetic efforts on behalf of our finance the University would hardly have come into being

Leeds Sewage Schemes

With a steady increase in the population of the city the sewage problem has been a pressing one for some time Extensive experiments have for years been carried out at Knowesthorpe under the chairmanship of Colonel Harding and these have included the bacteriological treatment of sewage Some years ago the corporation purchased the extensive estate of Gateforth near Selby, with the intention of instituting a sewage farm This would have involved the laying of a conduit, which it was proposed to build of brick, some 14 miles long, the route lying through the lands of Temple Newsam and over coal-fields The opposition to this was very strong and a committee of the House of Lords reported that it could not accept it as presented This was in 1902 and the sewerage committee called in expert engineering advisers to consult with the city engineer and arranged that their joint report should be submitted to an independent firm of experts This resulted in a modification of the Gateforth scheme being recommended By this screens and grit tanks would be provided at Knowesthorpe the present sewage station, and pumping plant to raise the sewage to a level of 85 feet The sewage would then be carried in three 47 inch steel pipes to Gateforth, where there would be settlement tanks and percolating filters and where there would be barren grounds for the disposal of the sludge on the land It would only be necessary in the first instance to lay down two thirds of the pumping plant and two of the three tubes This would deal with 80 000 000 gallons of sewage and would cost about £1 000 000, while the annual cost including interest and sinking fund on capital, would be about £60,000 or 7½*d* in the £ on the rateable value of Leeds Other schemes are being discussed and the corporation has shown its earnestness by taking the opportunity offered by the resignation of the city engineer to make two appointments, one officer having to devote himself exclusively to the work of a sewerage engineer at a salary of £1000 per annum The French delegates of the Seine department, who are spending a week in England to study our latest scientific methods for the disposal of sewage paid a visit to the Leeds works on May 3rd and all the methods adopted were shown to them

Memorial to Mr Christopher C Weatherill

Mr Thomas Brock has, I understand, accepted the commission of the board of the General Infirmary to execute the memorial to Mr Christopher Charles Weatherill, under whose will it may be remembered, the infirmary benefits so largely The memorial will probably take the form of a bas relief and will be placed in a ward to be named after the testator

The University of Leeds

On the invitation of the Mayor of Bradford the Marquis of Ripon, as Chancellor of the University of Leeds accompanied by Mr A G Lupton the Pro Chancellor, has recently had an opportunity of addressing a large and influential body of the leading citizens of Bradford and of appealing to them for their sympathy and support in increasing the foundation fund of the new university His lordship said that the aims and aspirations of the University of Leeds were much wider than those of a mere technical school and Mr Lupton pointed out that the university drew its students from a wide area for less than one fourth of its registered day students belonged to Leeds while no less than 58 students studying arts, science medicine and law were registered from Bradford —At a meeting of the Hull education committee a letter was read from the Pro Chancellor appealing to the various county boroughs for grants in aid of the work of the university The letter was referred to the higher education subcommittee with the hope that it would see its way to associate Hull with the university in connexion with its technical work

May 9th

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

Health Report of Merthyr Tydfil

THE annual health reports which relate to large industrial centres are always of interest and that of Mr D J Thomas, the medical officer of health of Merthyr Tydfil, is no

from Ayrshire to other sanatoriums until it could be ascertained that the treatment was likely to be successful. By a considerable majority, however, it was decided to go on with the plans. In deference to the opinions expressed by several of the large contributors another meeting of subscribers was held last week to consider whether building should be delayed until an annual income had been secured. The chairman stated that they had collected £12,200; when the hospital was in full working order it would have 40 beds, but in the meantime it was not proposed to have more than 12 beds, but the whole of the administrative block would be built and the estimated cost was £10,200. In the course of discussion Sir Matthew Arthur said that he did not think it was practicable to say they were not to build until they had an income, because he did not think they would get subscriptions towards maintenance until there was something to maintain. It was also pointed out that the sanatorium would appeal to a county with a population of 240,000 and there should be no difficulty in securing an annual income. Eventually it was decided that £10,000 should be spent in providing a sanatorium, including cost of site, and £2500 be ear-marked as maintenance reserve fund.

Northern Infirmary, Inverness.

At the annual meeting at Inverness on May 3rd Mr. C. M. Brown, honorary treasurer, reported that the ordinary revenue for 1904 amounted to £3548 and the expenditure to £5206, showing an adverse balance of £1658. The legacies received amounted to £1122. The average cost per patient last year was £19 11*s.* 10*d.*, showing a satisfactory decrease of £1 16*s.* 6*d.* per patient. The daily average of patients was 86·8, as compared with 76·3 in 1903. Mr. Alexander Grant expressed regret that inroads were being made on capital and Mr. Brown replied that they could only appeal to the public by way of remedy. Mr. D. Shaw, honorary secretary, showed that the committee of management had curtailed the expenditure last year to the lowest figures consistent with fairness to the patients. Mr. James Anderson said that the deficiency was not quite so bad as it usually was. For the past 40 years they had had invariably to draw upon legacies and it was perfectly legitimate to do so. There was really nothing alarming about the state of the funds. It would take about 22 years to exhaust the funds at their disposal. The reports of the secretary and the treasurer were adopted. Mr. Steele, banker, was added to the managers and house committee. Dr. W. A. Reid of Inverness was appointed house surgeon, he being the only applicant for the vacancy. Miss Macconnachie intimated her resignation of the post of matron, stating that she had accepted the appointment of matron-housekeeper of the Upper Banffshire Hospital at Dufftown. The managers tendered their thanks to Miss Macconnachie for her long services and the house committee was authorised to advertise for a matron and to report. It was remitted to the committee to continue the negotiations with the town council and district committee as to accommodation for fever patients.

May 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Mr. C. R. C. Tichborne, LL.D., D.P.H., L.R.C.S. Irel.

Professor Tichborne, who died at his residence, 15, North Great George's-street, Dublin, on May 1st, was well known to all the medical profession of that city, although he never engaged in general or hospital practice. He devoted his labours to analytical chemistry and was for a life-time chemist to the Apothecaries' Hall of Ireland which he represented for some years on the General Medical Council. He held the position of public analyst to many institutions and boards throughout Ireland. Many resolutions expressing the high esteem in which he was held by his colleagues were recently passed, more especially by the Apothecaries' Hall, the governors of which assembled at a special meeting on May 3rd. Similar resolutions were unanimously passed by the Royal Irish Academy and the Royal Academy of Music. Professor Tichborne was a highly skilled player of the 'cello.

Jervis Street Hospital, Dublin.

The annual meeting of the friends and supporters of Jervis Street Hospital, Dublin, took place on May 3rd. There was a very large attendance and the [illegible] Palles, who occupied the chair, [illegible] appeal to the public in suppor[illegible] this old-established institution.

Health of Belfast.

At the monthly meeting of the city corporation of Belfast, held on May 1st, it was reported that the number of cases of zymotic disease notified was more numerous than in the April report, typhoid and simple continued fevers being somewhat more numerous, whilst cases of diphtheria and erysipelas were slightly fewer in number. The death-rate from zymotic disease was rather higher, this being mainly attributable to measles, a disease which caused 32 deaths, those from all other zymotic diseases being 25. There had been no case of small-pox notified since Feb. 23rd and there was only one case in hospital which was still detained owing to complications. With reference to the new infectious diseases hospital, it was announced that it was proposed to put the whole institution under the care of a visiting physician and to have no resident medical officer or medical superintendent. Indeed, the house which was intended to be reserved for a resident medical officer has now been designated as a diphtheria ward.

Rainfall in Ulster during April.

In April rain fell in the north of Ireland on 26 days to the amount of 2·93 inches, which is more than the average (2·53). The total rainfall for this year is now 12·07 inches, which is over the average (11·74 inches).

Belfast District Asylum.

There are at present 1082 patients on the asylum register, 361 males and 369 females being at Belfast, 290 at Purdysburn, and 62 at Ballymena. It is very satisfactory to find that in all the new buidings at Purdysburn there are no extras except in the contracts and this is one for a corrugated iron roof costing £8 10*s*.

Quality of Milk and Meat.

[illegible]

for a holiday on the continent, where he visited Copenhagen, Berlin, and other cities to study the inspection of meat and the milk problem. Since his return to Belfast, about ten days ago, he has been giving the public through the local press his views on these questions. He is strongly in favour of the stamping of all meat by the municipal authorities, which is obligatory in the continental cities, and he urges the same course of action in Belfast. Dr. O'Neill also describes the Danish method of dairying as seen in Copenhagen, of which he appears to approve. A writer in the Belfast *Northern Whig* of May 9th congratulates Dr. O'Neill on the "rapid strides he has made on this subject." He was formerly in favour of sterilised milk, but the real principle of all scientific modern dairying is to procure a pure untreated and natural milk, this being done by perfect cleanliness in milking, by lowering the temperature of the milk after it comes from the cow, by medical and veterinary inspection, and by delivery in sealed cans or vessels. This is the Danish method, as was pointed out by writers in the Belfast papers long before Dr. O'Neill visited Copenhagen.

May 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Re-opening of the Faculty of Medicine.

I HAVE already kept the readers of THE LANCET *au courant* with the recent troubles at the Faculty of Medicine in connexion with the course of lectures given by M. Gariel which resulted in the closing of the Faculty of Medicine. After the Easter holidays the Faculty re-opened and M. Gariel began his course of lectures again without any notable incident. The Corporate Association of Students has addressed a manifesto to its members asking them for the future to refrain from individual protestations but to give such protestations an impersonal and [illegible] character so that the association may be able [illegible] collective and legal method of [illegible] hearers applauded him and M. Debove, the dean of the faculty, who was present at the lecture, made a short speech in which he thanked the students and expressed his satisfaction that this distressing incident had terminated so satisfactorily.

The Identification of Formol in Milk.

At the meeting of the Academy of Sciences held on April 17th M. Nicolas read a communication upon a Simple Test for Formol in Milk. The test will show the presence of formol in the proportion of 1 part in 500,000. The casein is precipitated and filtered and to the filtrate are added one or two crystals of amidol. The tube is then corked and at the end of a minute or two if formol has been added to the milk a beautiful green fluorescence shows itself. The reaction may be hastened by warming the fluid, but in this case it is better to remove all albuminous coagulable substances by the addition of a little acetic acid and subsequent filtration.

The Ophthalmological Institute of Adolphe de Rothschild.

A new ophthalmological institute has just been founded in Paris and is about to be opened. It is destined exclusively for the treatment of diseases of the eye and receives patients of any religion or nationality provided solely that they are indigent or necessitous. Gratuitous consultations are given every day from 9 to 11 A.M. and from 1 to 3 P.M. On Tuesdays, Thursdays, and Saturdays additional consultations are given from 7 to 8 P.M.

May 9th.

Obituary.

SIR JOHN SIBBALD, M.D. EDIN., F.R.C.P. EDIN.

BY the death of Sir John Sibbald the senior ranks of the medical profession in Edinburgh have lost one of their most esteemed and pleasant members. In his own department he had ungrudging admiration extended to him, whilst amongst a wider professional circle he impressed men by his friendly bearing, his quiet courtesy, his calm judgment, and a little vein of Scotch humour. He was not an old man, although he had reached a little beyond the allotted three score years and ten, and he had every appearance of living a good many more years when the mortal malady, which rapidly ran its fatal course, was first recognised.

Sir John Sibbald was an Edinburgh man and was born there in 1833. He received his medical education in Edinburgh where he took his M.D. degree in 1854. His position amongst students is indicated by the fact that he was one of the Presidents of the Royal Medical Society. After holding some general appointments he finally decided to devote himself to lunacy work, and became an assistant at the Royal Edinburgh Asylum under Dr. Skae. From that position he was selected for the medical superintendentship of the Argyle and Bute Asylum in 1862. Eight years afterwards he was appointed a deputy Commissioner in Lunacy for Scotland and on the death of Sir James Coxe he was created a Commissioner. This latter position he held until 1899 when he retired under the age limit. On his retirement he was honoured with knighthood in recognition of his valuable public and official services. His life was devoted to improving the management and the treatment of the insane in Scotland. He did much towards initiating and fostering the views regarding the nature of mental affections which now prevail in the profession generally; he was a pioneer in reducing the prison-like arrangements in vogue in asylums at that time. He from time to time contributed important papers to the *Journal of Mental Science*, his earlier ones dealing with the most advanced continental work bearing upon insanity. For a short period before he became deputy Commissioner in Lunacy he edited the journal mentioned. In 1877 he delivered the Morison lectures at the Royal College of Physicians, Edinburgh, taking as his theme Insanity in its Public Aspect; these were published in book form. Since his retirement he published an important pamphlet entitled "Plans of Modern Asylums for Insane Poor," and so highly was his opinion esteemed on this question that the Edinburgh District Lunacy Board appointed him its medical adviser when the board had to decide on plans for its new asylum.

The last prominent public work on which he was engaged was during last year when the International Congress for Home Relief met in Edinburgh. Sir John Sibbald was chairman of the executive committee and many of his friends in Edinburgh remember the warm interest which he displayed in all matters appertaining to the work of the congress. One of the latest, if not the latest, of his writings must be the pamphlet which he put in the hands of members of that congress on the "Relief of the Poor in Edinburgh, 1904." The pamphlet dealt with public relief under the Poor-law and with private relief rendered by voluntary agencies and was mainly intended for the enlightenment of foreign representatives.

Sir John Sibbald died in his house in Edinburgh and was buried in Warriston Cemetery. The funeral was largely attended by representative members of the Royal College of Physicians, by past colleagues on the Board of Lunacy, and by many private friends.

THOMAS CREED, M.D. ST. AND., M.R.C.S. ENG. L.S.A.

ON April 20th, at Boscombe, Hants, Dr. Thomas Creed passed away at the age of 79 years, after a lingering and painful illness which he bore with great fortitude. From 1851 he practised for 45 years at Greenwich and did yeoman's service amongst the poor of that neighbourhood. For more than 40 years of this long residence in Greenwich he was one of the honorary medical officers of the Royal Kent Dispensary; at the centenary of this institution in 1883 and upon the foundation of the Miller Hospital he was appointed honorary physician to the latter. This post he held till 1891. On his resignation in February of this year to retire to a quieter practice at Boscombe he was elected a consulting physician to the combined institutions and a testimonial, consisting of a purse of sovereigns with an address, was presented to him by the Very Rev. Canon O'Halloran on behalf of his numerous old friends and in appreciation of the respect in which he was held by his professional brethren. In 1876 Dr. Creed was President of the West Kent Medico-Chirurgical Society and took a keen interest in its meetings for many years.

Medical News.

UNIVERSITY OF OXFORD.—At recent examinations in the subjects indicated the following candidates have passed:—

Further examination in mathematics.—G. W. Carte, H. O. Gibson, S. B. Henson, R. E. Negus, A. Pearce-Gould, and A. S. Roe.
Elementary zoology.—P. P. W. Andrews, T. Bentham, J. L. Birley, A. Booth, G. W. Carte, A. R. Chavasse, H. E. Clarke, G. E. Downs, H. O. Gibson, H. Hinds, E. G. Martin, H. P. Newsholme, J. A. Noble, E. L. Pearce-Gould, E. W. M. H. Phillips, H. W. Scott-Wilson, C. J. G. Taylor, W. W. Wagstaffe, R. O. Ward, and T. S. Wright.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. L. Cappelletti has been recognised as *privat-docent* of Neurology and Psychiatry.—*Cadiz:* Dr. I. Gimeno Rodriguez has been appointed Professor of Clinical Medicine.—*Florence:* Dr. E. Dacco has been recognised as *privat-docent* of Dermatology.—*Kharkoff:* Dr. Penski, *privat-docent*, has been promoted to the Extraordinary Professorship of Topographical Anatomy and Operative Medicine.—*Königsberg:* Dr. W. Rindfleisch and Dr. E. Rantenberg have been recognised as *privat-docenten* of Internal Medicine.—*Munich:* Dr. E. Meyer has been recognised as *privat-docent* of Medicine.—*Vienna:* Dr. Raimann has been recognisd as *privat-docent* of Psychiatry.—*Zürich:* Dr. K. Jung has been recognised as *privat-docent* of Psychiatry.

CENTENARIANS IN CORNWALL.—Mrs. Oliver of Newquay, Cornwall, celebrated her 101st birthday on May 2nd, when she was the recipient of many presents and congratulations. Mr. James Carne of St. Columb Minor, near Newquay, entered his 100th year on May 3rd.

LITERARY INTELLIGENCE.—Messrs. Green and Son of Edinburgh will shortly issue "Methods of Morbid Histology and Clinical Pathology," by Walker Hall and G. Herxheimer. It will include all the new methods for blood and nervous tissues and a very full bibliography. Special types have been used in order to make the book convenient for laboratory work.

CHILDREN'S COUNTRY HOLIDAYS FUND.—His Royal Highness the Prince of Wales has again sent a donation of £5 to the honorary treasurer of the Children's Country Holidays Fund, 18, Buckingham-street, Strand, W.C., who appeals urgently for public support in order that many poor children may not be disappointed of their summer holiday.

DR. JAMES GREY GLOVER has received the following letter in reply to a communication made to the King in connexion with the celebration of the 102nd birthday of Miss Elizabeth Walker on May 8th:—

> Windsor, May 8th.
>
> I am commanded by the King to ask you to congratulate Miss [illegible] nent of her 102nd birthday and to say [illegible] hear that she is in enjoyment of such [illegible]
>

WOMEN AND FORENSIC MEDICINE IN RUSSIA.—From July 13th this year, says the *Bourse Gazette*, it is intended to settle the question of allowing women medical practitioners to act as experts in matters connected with forensic medicine. For this purpose a law, already drafted by the Minister of Justice, is under consideration by the Imperial Council, containing the provision that female medical practitioners may be accepted for independent medico-legal testimony as to women and children.

CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board met on April 27th at 6, Suffolk-street, Pall Mall, Dr. F. H. Champneys being in the chair. A letter was received from Dr. J. R. Kaye, county medical officer of the West Riding of Yorkshire, forwarding a communication from a conference of county medical officers held at Birmingham on March 10th last inquiring as to the construction of Rule E 2. This rule is as follows:—

> [illegible] a midwife must take with her. (*a*) an [illegible] a catheter, a pair of scissors, a clinical [illegible]; (*b*) an efficient antiseptic for disinfecting the hands, &c.; (*c*) an antiseptic for douching in special cases; (*d*) an antiseptic lubricant for smearing the fingers, catheters, douche nozzles, and enema nozzles before they touch the patient.

The Central Midwives Board was asked whether it was absolutely necessary for a midwife to carry all the apparatus mentioned in the rule and the opinion was expressed by the chairman of the Board that unless midwives fulfilled the requirements of the rules the question of striking them off the roll would arise. The decision of the Board was that Dr. Kaye should be informed that the Central Midwives Board possessed no dispensing power in the matter. The next business before the Board was the consideration of a letter from Dr. J. Niven, medical officer of health of Manchester, asking the Board as to the meaning to be attached to the word "malpractice" in Section 8 (2) of the Midwives Act. According to the Act the local supervising authorities are entrusted with the duty of investigating charges of malpractice on the part of any midwife practising within their area. After the question had been discussed for some time it was decided to send as a reply to the inquiry the statement that each case must be judged on its own merits. The Board then fixed the first examination for midwives to be held on June 27th and the second on Oct. 24th. In future four examinations would be held in each year, in January, April, July, and October. A letter was then read from the town clerk of Ramsgate inviting the Board to express an opinion as to whether the appointment of a Poor-law medical man as inspector of midwives would be suitable and proper. The members of the Central Midwives Board plainly stated that it was not one of their duties to express such opinions or to lay down rules but nevertheless the town clerk of Ramsgate was also to be informed after stating the above facts that the Board on the whole did not consider that such an appointment would be an advisable one. In the cases of three midwives who were charged with negligence the Board directed that they should be cited to appear before the Board. The first case of the three was reported on by Dr. Niven who stated that the local supervising authority in Manchester had found that a *primâ facie* case of negligence had been established against the midwife concerned. In the second case the clerk of the London County Council reported that the local supervising authority for the County of London had found that a *primâ-facie* case of negligence had been established against the midwife, and in the third case the local supervising authority for Aldershot was reported by Mr. W. B. Barclay to have found that a *primâ-facie* case of negligence had been established. 3976 women were passed under Section 2 of the Act and ordered for entry on the roll, the total number on the roll being 22,207.

METROPOLITAN HOSPITAL.—Princess Louise (Duchess of Argyll) on May 9th opened, at the residence of Lord and Lady Battersea, Surrey House, London, W., a two days' bazaar, which has been organised by the Ladies' Association of the Metropolitan Hospital, Kingsland-road, E., in aid of the general funds of that institution.

KING'S COLLEGE HOSPITAL.—The King's College Hospital removal committee, following the advice of its assessor, Mr. Rowland Plumbe, has awarded the first place to the design sent in by Mr. W. A. Pite, of the firm of Messrs. Pite and Balfour. The committee has also appointed Mr. Pite to act as the architect of the new hospital buildings.

UNIVERSITY OF CAMBRIDGE.—Mr. H. J. Waring, M.S., F.R.C.S., has been appointed an additional examiner in surgery for the M.B. and B.C. degrees.—Mr. W. Bateson, F.R.S., St. John's College, has been appointed deputy professor of zoology and comparative anatomy for the ensuing academical year.—At the Congregation on May 11th A. C. Ingram, St. John's College, was admitted by proxy to the degree of Doctor of Medicine.

DONATIONS AND BEQUESTS.—By the will of Mr. William Holborn £2000 are bequeathed to the Royal Hospital for Incurables, Putney, and £2000 to such hospitals for the sick in London as his executors shall select. In the event of their disagreeing this sum is to be paid to the London Hospital, Mile-end-road.—Mr. Joseph Proctor Mann has bequeathed by his will £100 each to Guy's Hospital, St. Thomas's Hospital, King's College Hospital, and Epsom College.

THE BACTERICIDAL ACTION OF HYDROGEN PEROXIDE ON THE GERMS IN WATER.—M. E. Bonjean has contributed to the Académie des Sciences the results (which are published in the *Comptes Rendus* for January, 1905) of a comparative study of the bactericidal action of commercial hydrogen peroxide solution and a solution of hydrogen peroxide prepared from calcium peroxide on the germs in the water of the Seine. Five litres of water were used for each test and the proportions of the bactericidal agents were varied. Nutritive gelatine cultures were made at intervals and counted after 15 and again after 30 days. The figures given show in a striking manner the greater bactericidal power of nascent hydrogen peroxide. It was found that 0·219 gramme of hydrogen peroxide in the form of the commercial solution was ca[illegible] hours, [illegible] at the [illegible] hours. These experiments also show that hydrogen peroxide in the nascent state has the advantage of rapidity of action over the ordinary solution.

MARY WARDELL CONVALESCENT HOME FOR SCARLET FEVER.—The report for the year 1904 of this useful institution, which is situated at Brockley-hill, Stanmore, shows that 131 patients were admitted to the home during the period under notice. The great proportion of the cases received comes from the class of small tradesmen, clerks, and mechanics, though the labouring class form a considerable number, and the medical officers of health of the various local boards send many patients who have been treated in isolation hospitals. Though there has been comparative freedom from scarlet fever during the past three years in and around the metropolis a season of epidemic may come at any time, but whether the cases be few or many there must be a staff prepared to meet the requirements of all emergencies. This, however, is impossible without adequate financial aid. The home is greatly in need of funds and the committee is urging the necessity of raising a small endowment fund for the purpose of covering a portion of the outlay on salary and wages, which is a [illegible] of the home. Subsc[illegible] Miss Mary Wardell and [illegible] Co.) may be sent to Messrs. Barclay and Co., Limited, 1, Pall Mall

East, London, S.W., or to Miss Mary Wardell, Stanmore, Middlesex, from whom further information can be obtained.

Royal College of Surgeons in Ireland.—A general meeting of the Fellows will be held on Saturday, June 3rd, at 1 o'clock, to receive the annual report of the council.—A meeting will also be held on Monday, June 5th, at 1 o'clock, pursuant to the provisions of the Charters, to elect a president, vice-president, council, and secretary of the College for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office should signify their wish by letter to the Registrar, at the College, on or before Tuesday, May 23rd.

Presentation to a Medical Practitioner.—At the annual dinner of the "Pride of Milverton" Lodge of Foresters held at Milverton (Somerset) on April 25th, under the presidency of Sir A. A. Hood, the chairman, on behalf of the members of the club, presented Mr. Charles Randolph, M.R.C.S. Eng., L.R.C.P. Edin., with a silver revolving breakfast dish, a soup tureen, and a pair of entrée dishes together with an illuminated address containing the names of 161 subscribers to the presentation, in appreciation of his services as lodge surgeon since the formation of the club in March, 1884.

Memorial to the late Dr. T. Morton.—The following committee has been formed in connexion with a proposed memorial to the late Dr. Thomas Morton: The Rev. Canon Duckworth, C.V.O., the Rev. W. H. Stone, Sir William H. Broadbent, Bart., K.C.V.O., General R. W. Lowry, C.B., Dr. S. H. Davson, Dr. W. Winslow Hall, Mr. F. W. Hunt, Mr. R. Newnham Davis, Mr. F. Jackson, Captain R. F. W. Ellis, Mr. F. E. Webb, Mr. H. Strousberg, Dr. R. R. Hardwicke, Mr. C. B. Allen, Mr. C. B. Lockwood, Mr. Seymour Lucas, R.A., Mr. John T. Taylor, I.S.O., Dr. G. Danford Thomas, and Mr. J. R. Cooper. Mr. Joseph White, of 7, Abercorn-place, London, N.W., is the honorary treasurer, to whom subscriptions may be sent.

Sussex Medical Benevolent Society.—The first meeting of this society was held at the Dispensary, Queen's-road, Brighton, on May 9th. Those present were Dr. C. F. Bailey, Mr. W. A. Bowring, Mr. G. Vere Benson (Lewes), Mr. W. Campbell (Hastings), Dr. W. C. Chaffey, Mr. Dodd, Dr. J. F. Gordon Dill, Mr. E. F. Frazer, Dr. W. H. Hillyer (East Grinstead), Dr. E. Hobhouse, Mr. W. R. Meyer (Hurst), Mr. G. Morgan, Dr. L. A. Parry, Mr. W. B. Prowse, Mr. C. S. Simpson, and Mr. J. Turton. Mr. Turton was elected president, Dr. J. C. Uhthoff was appointed treasurer, and Dr. Parry honorary secretary. The objects of the society (the membership of which is restricted to members of the medical profession) are to aid the widows and children of members dying in indigent circumstances, to assist members who are incapacitated from practising, and to help in the education of children of members so incapacitated. The secretary reported that 89 members of the profession in Sussex have already joined and he hoped now that the society had a good start the numbers would rapidly increase. The subscription is £1 1*s.* per annum and any medical man in the county is eligible for membership.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Ventilation of the House of Commons.

A small committee, consisting of Sir Michael Foster, Dr. J. S. Haldane of Oxford, and Dr. M. H. Gordon, is making a further inquiry into the ventilation of the House of Commons.

Medical Men and the Use of Alcohol.

When the Scotch Liquor Traffic (Local Veto) Bill was under consideration in the House of Commons on May 5th some discussion arose as to medical opinion in regard to the use of alcohol. One speaker quoted from a magazine article by Dr. R. Farquharson to the effect that when responsibilities are around us and the troubles of the world begin to close over our heads a cheering glass in strict moderation and at carefully selected times is of real use and can be defended both by physiology and common sense. Another speaker cited a statement to the contrary effect by Sir Frederick Treves. To all of which the Lord Advocate replied thus: "As for the medical evidence on the subject we must be driven to the conclusion that in this case, as in others, doctors differ. Sir Frederick Treves has said: 'The use of alcohol is absolutely inconsistent with a surgeon's work or with any work demanding quick and alert judgment.' That, surely, is a proposition too extreme to receive acceptance from ordinary reasonable men. And when we hear it stated that alcohol is a poison I wonder if honourable Members are aware that the minority report of the Royal Commission contained these words: 'We must recognise the fact that most people still regard alcohol as an ordinary article of diet which is only harmful if taken in excess.' It is idle to say that alcohol is a poison and nothing else and that the use of it is inconsistent with any work demanding acute and alert judgment."

Small-pox Return.

On Monday, at the instance of Sir John Batty Tuke, a return was ordered to be prepared showing each port or other sanitary district in England and Wales (exclusive of any district wholly or partly in London), in respect of which during the year ended March 25th, 1905, cases of small-pox have been reported to the Local Government Board; the number of such cases; and also, where the number reported has exceeded 100, the estimated amount of the expenditure incurred by the sanitary authority in consequence of the occurrence of such cases.

HOUSE OF COMMONS.

Wednesday, May 3rd.

Affairs of an Irish Asylum.

Mr. Sloan asked the Chief Secretary to the Lord Lieutenant of Ireland whether any change had been made in the arrangement which permitted Dr. Kelly, the Roman Catholic Bishop of Cloyne, to fit out at the public expense a vacant industrial school at Youghal for the reception of insane patients and whether Dr. Kelly was paid a capitation grant for each patient; whether he was aware that the patients were nursed by nuns who had had no previous training in such duties, that there was no resident medical superintendent, and that the medical care of the patients was under the control of a visiting physician who had had no previous training in the diseases of the insane, although visiting physicians had been allowed to die out in all the other Irish and British asylums; that the house built at Youghal for the resident medical superintendent was occupied by a chaplain whose chief duty was to look after the spiritual welfare of the nuns; that the Under Secretary for Ireland had already remonstrated with the Bishop of Cloyne against these irregularities; if so, whether they had the approval of the inspectors; and whether such steps as were necessary would be taken to restore the lunatics now in the charge of the Bishop of Cloyne to proper supervision and control.—Mr. Long answered: In reply to my honourable friend's question of Feb. 23rd last Mr. Wyndham made a very full statement on this matter which substantially covers the ground of the present question. It is only necessary to repeat that the two points connected with the administration of this auxiliary asylum in regard to which the inspectors have raised objection are: first, the appointment of a visiting instead of a resident medical officer; and, secondly, the resolutions of the committee of management relieving the resident medical superintendent of the Cork Asylum from all responsibility for the discipline and domestic management of the auxiliary. In regard to the first the consent of the Lord Lieutenant to the appointment of a visiting medical officer has only been given as a tentative measure which will be open to reconsideration if the arrangement should prove defective; and as to the second, the committee has been informed that the resolutions are illegal and have been called upon to correct the illegality. The Under Secretary has made representations on the subject to Dr. Kelly, Bishop of Ross, who is a member of the committee. The capitation grant is payable to the county council.

Isolation Hospital Accommodation at Wanstead and Woodford.

Mr. Louis Sinclair asked the President of the Local Government Board whether he was aware that Wanstead and Woodford were adjoining urban districts having populations of 9000 and 14,500 respectively; that Wanstead had ample isolation hospital accommodation and Wood- [illegible] inquiry was held in November last under the [illegible]), at the instigation of Woodford alone and in [illegible] onstrance of Wanstead; that His Majesty's [illegible] vour of the Local Government Board making a [illegible] order for the formation of a joint hospital board for the two districts; that a letter from the Wanstead urban council and a petition from the ratepayers had been sent to the Local Government Board against the order being made, Wanstead desiring to ret[illegible] its own hospital and to maintain its own patients; and, if so, wheth[illegible] he would undertake, in the circumstances, that the Board wou[illegible] decline, at the instance of Woodford alone and in face of the oppositi[illegible] of Wanstead, to make a compulsory provisional order (subject to c[illegible] firmation by Parliament) for the formation of a joint hospital board [illegible] the districts of Wanstead and Woodford combined.—Mr. Gra[illegible] Lawson answered. He said: I am aware of the facts of this ca[illegible] which are generally as stated in the question. The matter is n[illegible] under the consideration of the Local Government Board but I cann[illegible] at present state what its decision will be.

Thursday May 4th.

Arsenic in Beer.

Dr. Hutchinson asked the President of the Local Government Boa[illegible] what steps had been taken by the officers of the Inland Revenue to t[illegible] the various materials used in the manufacture of beer, to obtain return of the specific ingredients so used, and to ascertain to wh[illegible] extent, if any, they were found to be contaminated with arsenic, a[illegible] whether any standard of purity in beer had been laid down by t[illegible] Inland Revenue.—Mr. Austen Chamberlain, who replied, said: [illegible] respect to the first three portions of the honourable Membe[illegible] question the procedure of the Board of Inland Revenue in exercisi[illegible] control and inspection over the ingredients which might conta[illegible] arsenic and which are used in the manufacture of beer [illegible] that provided for in the Revenue Act of 1888 as extended [illegible] October, 1901; the revenue officials have caused frequent samples be taken of other ingredients than those immediately specified in the Act named. They have tested not only glucose and invert sugar but also caramel, malt, hops, and a number of brewers' worts, and in cases where beer regenerators and yeast foods have been found arsenical the manufacturer has either been cautioned or sanction to the use of the

Non-Compliance with the Vaccination Acts at Brighton.

Mr. WEIR asked the President of the Local Government Board whether he was aware that the vaccination officer for the borough of Brighton had recently obtained warrants of distress upon the goods of several persons in the borough for alleged non-compliance with the terms of the Vaccination Act, 1898; and whether, seeing that this officer was employed by the Brighton board of guardians and paid by that body, he would state why they were not communicated with before such measures were resorted to.—Mr. GRANT LAWSON answered The Local Government Board has not received any information as to the matter referred to, but in its opinion the application for a distress warrant forms part of the proceedings for the enforcement of the Vaccination Acts. These proceedings the vaccination officer is empowered to take without previous communication with the guardians.

As already pointed out the isolation of small pox "contacts" cannot be effected except with the consent of such persons. In ordinary circumstances it is held to be unnecessary to isolate the inmates of dwellings invaded by small-pox in districts in which the sanitary laws are properly administered and vaccination is efficiently carried out. I see no reason therefore for legislation on the subject.

Uncertified Deaths in Scotland.

Mr. WEIR asked the Lord Advocate whether he would state the number of uncertified deaths in Scotland and Ireland respectively for each year since 1900.—Mr. SCOTT DICKSON answered: The number of deaths from uncertified causes in Scotland during 1900 was 2757; during 1901, 2392; and during 1902, 2180. The figures for 1903–04 are not yet available. For information as to the Irish figures the honourable Member will probably apply to the Secretary to the Lord Lieutenant.

The Departmental Committee on Poor law Medical Relief.

Mr. MUNRO-FERGUSON asked the Lord Advocate whether he proposed to take any further action upon the report of the Departmental Committee on Poor-law Medical Relief.—Mr. SCOTT DICKSON said: A Bill is in course of preparation which, as at present proposed, will embody certain of the recommendations of the Departmental Committee on Poor-law Medical Relief.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BRETT, EDWARD SEYMOUR, M.B., Ch.B. Edin., has been appointed Assistant Medical Officer to the Mental Hospital at Seacliff, New Zealand.

CHERRY, T., M.D. Melb., has been appointed Acting Director for Agriculture in Victoria, Australia.

COUTTS, D., M.B., C.M. Glasg., has been appointed Assistant at Kingseat Asylum, Glasgow.

DOUGLAS, ALEXANDER, M.B., M.S. Edin., has been appointed a Port Health Officer, Oamaru, New Zealand.

EARLE, ROBERT CHARLES, M.R.C.S., L.S.A., has been appointed Health Officer of the Port of Wanganui, New Zealand.

FARRER, CLAUDE ST. AUBYN, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been re-appointed Clinical Assistant at the Samaritan Hospital for Women.

HINGSTON, CHARLES ALBERT, M.D., B.Sc. Lond., M.R.C.S. Eng., has been appointed Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

JUDSON, J. E., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Assistant Medical Officer to the District Infirmary and Children's Hospital, Ashton-under-Lyne.

KELLY, JAMES PATRICK, M.B., has been appointed Acting Officer of Health of the shire of Wyndham, Victoria, Australia.

MAILER, RAMSAY, L.R.C.S. Edin., has been appointed Medical Superintendent of the Ararat Lunatic Asylum, Victoria, Australia, *pro tem.*

MAKGILL, ROBERT HALDANE, M.B. Edin., D.P.H. Cantab., has been appointed Bacteriologist to the Health Department, New Zealand.

NEIL, J. HARDIE, M.B., has been appointed a Medical Practitioner under the Workers' Compensation for Accidents Act, Auckland, New Zealand.

NEWELL, JOHN ALEXANDER, B.A., M.B., B.Ch., has been appointed Surgeon to H.M. Prison at Lyttelton, New Zealand.

PARKES, W. H., M.B., Ch.M. Edin., has been appointed Honorary Medical Officer to the Veterans' Home, Auckland, New Zealand.

TRENFIELD, GEORGE HENRY, M.R.C.S., L.R.C.P. Lond., has been appointed, *pro tem.*, Medical Officer of the Eighth District by the Bristol Board of Guardians.

WALL, VIVIAN F., L.R.C.P., M.R.C.S., L.S.A., has been appointed Honorary Anæsthetist to the Western Ophthalmic Hospital, Marylebone-road, W.

WATERFIELD, WILLIAM HENRY, L.R.C.P. & S. Irel., has been appointed Chairman of the Children's Committee of the Devonport (Devon) Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AUCHTERHOUSE, SIDLAW SANATORIUM.—Medical Superintendent. Salary £250 per annum.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 and fees.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, Birmingham.—Clinical Assistant. Honorarium at rate of 52 guineas per annum.

BODMIN, CORNWALL COUNTY ASYLUM.—Junior Assistant Medical Officer. Salary £135 per annum, rising to £155, with board, lodging, &c.

BRISTOL GENERAL HOSPITAL.—Assistant House Physician. Salary £60, with board, residence, &c.

BROADMOOR, BERKS, STATE CRIMINAL LUNATIC ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £200, rising to £225 per annum, with quarters, coals, gas, and attendance.

CANCER HOSPITAL, Fulham-road, S.W.—Assistant House Surgeon for six months, renewable. Salary £70 per annum, with board and residence.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—House Surgeon. Salary £100 per annum, with rooms, board, washing, and attendance. Also Assistant House Surgeon. Salary £60 per annum, with rooms, board, washing, and attendance.

DARENTH, NEAR DARTFORD, METROPOLITAN ASYLUMS BOARD ASYLUM.—Senior Assistant Medical Officer, unmarried. Salary £250 per annum, rising to £300, with rations, lodging, attendance, and [illegible]

[illegible] HE COLLEGE OF HYGIENE AND PHYSICAL [illegible] Man. Salary £300 per annum.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician. Honorarium of £25 at completion of six months' approved service, with board and residence.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—House Physician and House Surgeon. Salary £80 respectively, with board, residence, and washing. Also Assistant House Surgeon. Salary £70, with board, residence, and washing. Also Eight Clinical Assistants.

EXMINSTER, DEVON COUNTY ASYLUM.—Junior Assistant Medical Office [illegible] 155.

GRIMSBY [illegible]—Resident House Surgeon. Salary accor[illegible] lodging and washing.

GUY'S HO[illegible] Value £100.

HULL, ROYAL INFIRMARY.—Hou[illegible] Salary 80 guineas per annum, with boar[illegible]

LISTER INSTITUTE OF PREVENTIVE MEDICINE.—Assistant Bacteriologist to the Serum Department, Elstree, Herts. Salary £200 per annum, with rooms.

Births, Marriages, and Deaths.

BIRTHS.

BROOK.—On May 6th, at Fellows-road, South Hampstead, N.W., the wife of J. H. E. Brock, M.D., F.R.C.S., of a daughter.

COLLINGWOOD.—On May 9th, at Ashton-under-Lyne, the wife of Captain Percy H. Collingwood, R.A.M.C., of a daughter.

MARRIAGE.

THOMSON—HENDERSON.—On May 2nd, at Waltham Abbey, by the Rev. F. B. Johnston, vicar of the parish, Wm. Thomson, M.B., C.M., to Jeannie Brodie, second daughter of the late John Brodie Henderson, M.D.

DEATHS.

PAINE.—On May 5th, at Lynwood, Alverstoke, Hants, William Paine, M.R.C.S., aged 68 years.

SPICER.—On May 7th, Frederick Spicer, M.R.C.S., late Colonial Surgeon, South Australia, of Carleton-road, Tufnell-park, N., aged 85 years.

WALKER.—On May 7th, at 54, Maddox-street, London, W., of acute pneumonia, James G. Walker, M.B., C.M. Edin. Funeral service at St. George's Church, Hanover-square, W., on Saturday, May 13th, at 10.30 A.M. Friends will kindly accept this, the only, intimation.

WHITE.—On May 9th, at Carlton-hill, N.W., Charles White, Lieutenant-Colonel R.A.M.C., aged 64 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE WAYS OF THE QUACK

As most of our readers know there is an election to the foundation of Epsom College to be held shortly Details of the candidates for election with requests for votes are being sent out in the usual way One medical man who is canvassing on behalf of a candidate in whom he is interested has been sending out circulars and for this purpose purchased a number of envelopes Incidentally he cut one of these envelopes open and was naturally much surprised to find the interior side of the front of the envelope printed as follows:—

The Secretary,
Drouet Institute,
11, Marble Arch,
London, W

This is, we have no hesitation in saying, an abominable method of advertising In this particular instance anything better calculated to ruin the candidate's chance we cannot conceive for any medical man seeing a circular sent out with the apparent connivance of the Drouet Institute would at once throw it into the waste-paper basket A new terror will be added to life if the unhappy citizen cannot even buy a packet of envelopes without having the claims of quacks thrust upon him and we wonder that any respectable vendor of envelopes should *consent to sell such goods as these upon which we now comment*

MEDICAL MATTERS IN THE LAY PRESS

To the Editors of THE LANCET

SIRS,—I am aware that it is not your practice to take notice of ignorant statements on medical matters by the lay press but it occurs to me that you may be interested to a slight extent on reading the inclosed comment on the Devereux case which appears in one of your contemporaries It will be needless to remind you that in the Chapman (Klosowsky) case antimony was the poison used It is to be hoped that readers with a taste for experiment will not be tempted to use strychnine for "preserving purposes

> *The post mortem —Bodies well nourished Strychnine had preserved them* —The awful contents of the trunk were not laid bare until it reached the mortuary Here the doctors had a surprise No unpleasant odour came from the remains The bodies were frightfully huddled together but were in excellent preservation It was also noticed that both the woman and children were well nourished Absence of bruises indicated the agent employed by the murderer—poison the perfect state of preservation of the bodies pointed to the poison used—*strychnine This is a deadly* poison but it preserves the remains of the victims In the case of one of Chapman's victims, exhumed at Warrington after being buried over a year, it was found that strychnine had kept the body in excellent condition

False information given to an individual may *mislead one person* only but in the case of a newspaper boasting of 1,000 000 readers each error published must be multiplied by 1 000 000 or so One reads a deal about compulsory education in the present day but I read a short time ago that a microbe is 'a minute insect.' A report of an inquest tells me that the deceased died of "serious' apoplexy (a logical if ignorant conclusion) Appendicitis, according to a halfpenny newspaper, is "inflammation of the kidneys' An enterprising weekly, describing a successful operation, gravely asserts that the subject had had his "appendage' removed and is doing well

I am, Sirs, yours faithfully,
April 22nd, 1905. B A. OXON

"LIQUOZONE"

IN response to a number of inquiries which have reached us from our readers as to the composition of 'liquozone we may say *that we have submitted a sample bought in the open market to our* analytical department and the result of the analysis shows that it is simply a weak solution of sulphurous acid gas It contains, also, probably as incidental impurities some free sulphuric acid, hydrochloric acid, traces of iron, and colouring matter The total constituents other than water amounted to 1 per cent, the sulphur dioxide to 0 25 per cent. These results are perfectly consistent with the statement made by the makers that "the gas [in liquozone] is derived solely from the following substances which include the best producers of oxygen and producers of other germicidal gas manganese dioxide, potassium chlorate, sodium nitrate, flowers sulphur, and red sanders None of these substances is put into the product, nothing but the gases derived from them And nothing whatever enters into liquozone save these gases and the liquid used to absorb them, plus a touch of colour There is nothing in the nature of ozone in the liquid and, in fact, neither *ozone nor oxygen could exist long in* an excess of sulphurous acid gas The process above described is, of course a very laborious, not to say wasteful, way of producing a weak solution of sulphurous acid gas, but the long list of superfluous chemicals is no doubt calculated to convey an impression of the mysterious virtues of the precious fluid and besides "a process requiring large apparatus and from eight to 14 days time' is doubtless held to justify the impudent price asked for a large sized bottle—viz, 2*s* 3*d* The vaunted cure-all properties of liquozone are a snare and a delusion

DIFFICULTIES UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT

To the Editors of THE LANCET

SIRS,—The public health and housing committee of the Poplar borough council desire me to reply to the letter under the above heading, signed ' Thomas Marshall, which appeared in THE LANCET of April 29th The committee appreciate the fairness with which the Editors of THE LANCET have made their criticisms on the evidence laid before them on one side, and in justice to the medical officer of health of this borough and themselves they desire me to explain the circumstances and to state the committee take the full responsibility for the

case It is essential that
or their own notifications,
officer to satisfy himself, if

necessary with the aid of an independent medical practitioner, with regard to any such notifications, but it has also been the practice in any case of doubt, after a second practitioner has been called to a case, for the medical officer of health, if desired, to attend and state his opinion I inclose copy of the correspondence in the case, from which you will be able to judge *as to the* accuracy of the statements of Mr Marshall Had Mr Marshall stated the circumstances in his first letter to the medical officer as fully as in his letter to you and explained that a second medical practitioner had been consulted the medical officer would have had no hesitation in seeing the case and advising thereon I am, Sirs, yours faithfully,

Council Offices, Poplar, E, LEONARD POTTS,
May 9th, 1905 Town Clerk

[INCLOSURE]

DEAR SIR,—Would you kindly oblige me by looking at a case I have at ——— *Road? It is in a man 22 years of age, a clerk at* ——— Station It started as typical *chicken pox* but to me it is more than suspicious Yours truly,
(Sgd) THOMAS MARSHALL
Medical Officer of Health Poplar

18th April, 1905.

Dr Thomas Marshall, 82 Devons road

DEAR SIR,—I am in receipt of your note respecting a case in ——— Road If you think the patient is suffering from small pox you must notify the same to me as such, if you have any doubt about the case I would advise you to call in a brother practitioner as my committee consider it no part of my duty to diagnose diseases for medical practitioners

Yours faithfully,
(Sgd) FREDK WM ALEXANDER,
Medical Officer of Health

(The words omitted in above letters have been deleted by us to save any disclosure of the patient's identity —ED L)

Mr Marshall replied to Mr Alexander in unnecessarily strong terms, being incensed at Mr Alexander's refusal of assistance We do not publish the letter but after being addressed in such a manner Mr Alexander could hardly be expected to do more in the matter Speaking generally however every practitioner who seeks the help of the medical officer of health of his district ought to obtain it, and obtain it promptly The following is the resolution of the council of the metropolitan borough of Poplar on the matter It bears the date April 11th, 1905, and has reference to an unfortunate case of mistaken diagnosis —

> "That in the opinion of the council Mr was most improperly notified as suffering from small pox on the 22nd day of January last, that his removal from home was then effected without any valid reason and that his return thereto on the following day after examination by the medical officers of the Metropolitan Asylums Board was amply justified, in consideration whereof, and the frequency and peril of such abortive notifications and illegal removals, the council hereby instructs its medical officer of health in every future case of notification to satisfy himself if necessary with the aid and confirmation of *an independent and reliable medical practitioner*, that such notification is in all respects according to law, and that no reasonable apprehension need be entertained of serious harm resulting (to the patient affected thereby) from isolation by removal also the council orders that whenever such reasonable *apprehension* is entertainable isolation without removal shall be in the best possible manner accomplished"

MOSQUITO NETS

Mr Alan Field the author of a little book called 'Verb Sap on Going to West Africa, writes to us to point out that the catalogues of many firms who cater for members of the public *who are going to* the tropics give illustrations of mosquito nets over a bed which are not only wrong but dangerous. The net is represented as being *outside* the supports not tucked in and reaching nearly to the ground so that it incloses the bottom of the bed and leaves a small open *space between its bottom edge* and the floor Such an arrangement is useless and, as Mr Field points out, the bottom of the net should always be tucked in under the mattress and should be hung *inside the* support. It is a good plan to have the lower two feet of the net all the way round made of thin calico or linen. This not only prevents the tearing of the net by the tucking in but if the sleeper should in his sleep roll over so as to touch the netting he will touch the calico or linen which has no holes in it and a mosquito therefore is unlikely to bite the portion of the body which touches the netting. We do not know the firms to which Mr. Field alludes, but they should certainly revise their catalogues.

TRAFFIC IN MEDICAL PRACTICES.

To the Editors of THE LANCET.

SIRS,—As one of the largest advertisers in your paper for 30 years past of medical practices for sale I presume I may claim the honour of sharing with yourselves the credit of inserting advertisements, 99 per cent. of which are, according to the letter in the *Daily Mail*, swindles. I would simply say in refutation of such a slanderous statement that every advertisement I insert is absolutely *bonâ fide*, and I do not believe for a moment that you or any other respectable paper would insert any advertisement you had any doubt about. The statement that "advertisement columns teem with notices of sale of practices of £500–£2000 a year" is absolutely false. I fail to see in your columns last week a single practice of £2000 a year. Who are we to recognise as the "heads" of the profession? It is common knowledge that many of the leading physicians and surgeons do their best to procure and recommend partnerships and practices for their less fortunate colleagues. Why should not members of an honourable and honoured profession who have toiled for perhaps 30 or 40 years to acquire a valuable connexion be entitled, when compelled by adverse circumstances to retire, to obtain the fair value for their goodwill. Purchasers who are disappointed with their bargain as a rule have only themselves to blame for failing to take precautions before purchase, for, as you justly remark in your annotation, no one but a fool would purchase without an expert examination of books. By kind permission of the *Daily Mail* I hope the medical profession and their representative papers will still be able to exist as before. As regards the question of the purity of all advertisements I venture to ask why the *Daily Mail* is accepting hundreds of pounds for display advertisements booming a certain concoction *guaranteed* to cure almost every disease in existence, and which the owners have spent £20,000 to produce! I am, Sirs, yours faithfully,

Adam-street, W.C., May 9th, 1905. PERCIVAL TURNER.

DISTINCTIVE BADGES FOR CERTIFICATED NURSES.

MISS Dorothy A. Davey, a certificated obstetric nurse, writes to us from Streatham suggesting that every certificated nurse should wear a distinctive badge which "would obviate the necessity for any other registration of nurses or uniform as the public could tell at a glance whether or not the owner of the uniform had earned the right to wear it." Such badges, she says, should only be supplied by Government to nurses on production of their certificates. To show how the badges could be made Miss Davey inclosed a card of coloured illustrations showing six circular silver or bronze bands or rings (which a half-crown piece would nearly cover), four of the bands encircling a coloured St. George's cross, one a white St. George's cross, and one a fine line white St. Andrew's cross. The badges with bronze bands would be for fever nurses. The St. George's crosses are coloured red, blue, and green respectively for four and three years' certificates, two years, and one year. The white St. George's cross is reserved for the midwifery certificate and the fine line white St. Andrew's cross for the obstetric nursing certificate, and where these two certificates are combined the two crosses are combined. For the full training and midwifery the red St. George's cross is superimposed with a small white St. George's cross. Miss Davey adds that each coloured cross could be used in conjunction with the white cross and that on the reverse of the ring should be the owner's name.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—I have no doubt that it is far better for B to lose a patient than to commit a breach of a rule which admittedly lies at the foundation of consultations between neighbouring practitioners. If C will not employ A and B refuses to take the case he can, of course, employ any other practitioner he may choose, but in all probability, when he finds that B maintains his point, he will rather have A than a complete stranger. I am, Sirs, yours faithfully,

May 9th, 1905. EQUITY.

THE PREVENTION OF CONSUMPTION.

WE have received a copy of the *St. Paul Pioneer Press* of April 2nd, containing a report of an address on "The Great White Plague," delivered by Dr. Reginald B. Leach in St. Paul, Minnesota, U.S.A., on March 29th. The address, which fills 14 columns of the newspaper, is illustrated with several views of sanatoriums. Dr. Leach urges that the State of Minnesota should give much increased support to its sanatoriums. His proposal is that the State should lay out $200,000 for the sanatorium treatment of the poorer class of tuberculous patients and that this sum should be supplemented by a further appropriation of not less than $25,000 for "pay beds," in order that citizens who are able and willing to pay may obtain sanatorium care in Minnesota. He predicts that in the course of time the legislature will provide for the compulsory segregation of tuberculous patients.

LUTON'S ARTIFICIAL SERUM.

To the Editors of THE LANCET.

SIRS,—I should feel much obliged if your readers could give me information as to results obtained in the treatment of tuberculosis when "Luton's artificial serum" is employed.

I am, Sirs, yours faithfully,

F. S. D. HOGG, M.R.C.S.Eng., &c.

Rickmansworth, Herts, May 8th, 1905.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can any reader kindly give the information of a permanent home where a young male adult with impaired motion of his right side could be placed? His friends are small dairy farmers and could contribute a moderate sum weekly for his maintenance.

I am, Sirs, yours faithfully,

May 3rd, 1905. RUSTIC.

MEDICAL TITLES.

To the Editors of THE LANCET.

SIRS,—Is it fair that one man passes an examination in medicine, surgery, and midwifery and gets L.S.A. only after his name and another who passes an examination in the same subjects is enabled to put after his name L.R.C.S., L.R.C.P.E., L.F.P.S.G., L.M.?

I am, Sirs, yours faithfully,

May 2nd, 1905. M.R.C.S., L.S.A.

Surgeon.—In our view a house surgeon, as much as any other gentleman, is bound by any agreement that he makes. We cannot say whether in any particular circumstances the authorities of a hospital would have legal redress for the infringement of a bond not to practise in the neighbourhood. An answer to such a question can only be given by a lawyer after consideration of the particular facts.

B.A.W.—We do not remember the case. Questions of privilege have frequently been debated in our columns, notably on Sept. 12th (p. 767) and 26th (p. 906), 1903; and Jan. 16th (p. 181), Feb. 20th (p. 537), Sept. 10th (p. 800), and Nov. 26th (p. 1513), 1904.

D.—We do not answer anonymous letters.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET *Offices, 423, Strand, London, W.C.*

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An Address

ON

THE FINANCIAL RELATIONS BETWEEN THE LONDON HOSPITALS AND THEIR AFFILIATED MEDICAL SCHOOLS; AND THE BEARING OF THESE RELATIONS ON MEDICAL EDUCATION.

Being the Annual Oration of the Medical Society of London, delivered on May 15th, 1905,

BY HENRY MORRIS, M.A.LOND., F.R.C.S.ENG.,

SENIOR SURGEON TO THE MIDDLESEX HOSPITAL; MEMBER OF THE GENERAL MEDICAL COUNCIL; MEMBER OF THE COUNCIL (LATE VICE-PRESIDENT AND CHAIRMAN OF THE COURT OF EXAMINERS) OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. PRESIDENT AND GENTLEMEN,—Until the last decade or so the medical schools in London were practically self-supporting. Year by year, however, the progress of medical sciences, the addition of fresh subjects of study, and the introduction of more exact methods of demonstration into medical teaching, have added to the expense of medical education. At length, despite the increasing personal self-sacrifices of the teachers, it was found that the schools were making annual deficits and that it was no longer possible for them to continue their work without assistance, in one form or another, from the funds of their respective hospitals. Two schemes were put forward for relieving the schools and the hospitals of this burdensome expenditure—one a self-supporting amalgamation scheme; the other the establishment, by an appeal to the public for funds, of an Institute of Medical Sciences in connexion with the University of London. Meanwhile questions were raised as to the justifiability of applying funds given to the hospitals to the purposes of the medical schools attached thereto.

When, in accepting the invitation of the council of the Medical Society to deliver the annual oration I proposed as my subject, "The Financial Relations between the London Hospitals and their Medical Schools," there had been, so far as I was aware, no rumour of the appointment by the President of King Edward's Hospital Fund for London of the "Medical Schools Committee." As this committee, consisting of Sir Edward Fry as chairman, Lord Welby, and the Bishop of Stepney, has made its report and as the information contained therein is far more complete than I could otherwise have obtained, I shall, in addressing you this evening, constantly allude to the report itself and to the evidence on which the report is based.

The terms of reference and instruction to the committee were the following:—

[illegible] may advise the committee will be in operation on Jan. 1st, 1905.

The circumstances which led up to this inquiry were, no doubt, threefold: 1. The Antivivisection League for eight years had been protesting against the hospitals granting subsidies to their associated medical schools, solely and entirely on the ground that the practice of vivisection had been carried on in the medical education given in some of these schools. 2. Certain vague statements and arguments, founded on the increase in the population of London in receipt of hospital treatment, out of proportion to the increase in the whole population of London, and which increase has been attributed to the action of the medical staffs of hospitals with schools attached to them. 3. An appeal from an anonymous donor (who had offered on certain conditions a gift which would have increased the permanent income of the Fund by £4666 a year) to the Prince of Wales asking that, as President of the King's Fund, His Royal Highness would endeavour to prevent any of the Fund being diverted to medical education.

In reply to the first of the three questions submitted to it, the committee has very clearly indicated the intimate and complex relations which have grown up between the hospitals and schools. It points out that in the year 1903—the last year for which the accounts were then complete—eight of the hospitals in its judgment made contributions, either directly or indirectly, or both, to the schools out of the funds of the hospitals. The eight hospitals were Charing Cross, the London, the Middlesex, St. Bartholomew's, St. George's, St. Mary's, St. Thomas's, and the Westminster. In the case of Guy's Hospital and the Royal Free Hospital the committee doubts whether, in consideration of all the circumstances, the schools can be regarded as deriving any pecuniary benefit from the hospitals, but it has no hesitation in saying that no money given or subscribed to University College Hospital or to King's College Hospital was in the year 1903 contributed directly or indirectly by the hospital for the maintenance of medical education.

The committee was not required to justify, to censure, or to condemn such contributions but if we may read between the lines of several of the questions put by the committee to certain of the witnesses the inference is that, in the opinion at any rate of Lord Welby and the chairman, aid given to the medical schools by the hospitals under certain conditions is not a diversion of the funds.[1] Their remarks are in complete accord with one's own experience of the wishes of donors to hospitals, whose object is that as much good as possible should be done for the afflicted poor. The application of the knowledge gained in the wards to the relief of the sick poor beyond the walls of the hospital no doubt appeals as strongly to their charity and intelligent sympathy as the alleviation and restoration to health of the comparatively few who come within its walls. Yet the report makes no allusion to this aspect of the matter in replying to Question 3. It seems to me, however, to be one of the "general considerations applicable to all hospitals having medical schools," which might have been brought forward in justification of devoting some part of the funds of the hospitals to the needs of the medical schools. Hospitals as the arena of medical education minister to the needs of the sick poor to a manifoldly greater extent through the widely scattered medical practitioners who have been trained therein than through the medical and surgical staffs immediately in charge of the wards and out-patients of the hospitals.

The founder of a well-known Paris journal is reported to have said that a carriage accident in the Rue Tronchet is better "news copy" than an earthquake in China. What M. Villemessant meant to imply was, of course, that human nature is much more easily affected and impressed by events which occur near by than by those which happen at a distance; and [illegible] more interested [illegible] than by the mis[illegible] never seen or previously heard of. But we need not take it for granted that every subscriber and donor to a hospital is under the sway of this natural apathy and unconcern for sufferers afar off; yet, unless it be so, we have no right to assume that hospital managers divert the funds intrusted to them for the relief of the sick poor, if they vote some portion of those funds for the maintenance and improvement of medical education.

A very important matter bearing both on the difficulties of the medical schools and the supply of trained practitioners for the sick poor throughout the land, is the necessity of keeping the cost of medical education within the limits of moderate incomes. The medical profession is chiefly recruited from persons of moderate means and moderate expectations; it does not attract many of the richer classes; the remuneration in some districts scarcely repays the qualified medical men and to add to the cost of entry into the profession would tend to encourage irregular practitioners. Suppose the medical schools agreed on raising their fees to a figure adequately to remunerate the teachers after paying all other expenses of upkeep, rent, service, &c., only the richer men could enter the profession. Then this would happen: the very poor and the paupers would be unable to obtain medical aid owing to the reduction in the number of medical men. There would arise the outcry that the poor were allowed to die from curable diseases for want of proper advice and treatment; and the State or the ratepayers would have to subsidise the existing medical schools to induce them to lower their fees, or would be obliged to establish medical schools of their own. Possibly the State would have to educate medical men for Poor-law and club practices just as it provides the professional education of naval and military officers, the training of school teachers, and quite recently the instruction in tropical medicine of Colonial medical officers. The untoward consequences of making the fees for medical education high enough to enable the schools to continue to be self-supporting (even after the remuneration of the teachers had been reduced in many instances to a vanishing point) have never been lost sight of by the committees of the medical schools. None know better than they that "there can be no doubt of the desirability in the largest interests of the public of rendering medical men of high character and of good professional capacity, generally accessible to all classes of the population."[2] Nor could any stronger reason than this be given why the deficits of the medical schools should be made good by external pecuniary aid.

---

[1] See Minutes of Evidence, Questions 837, 931, 937, 932, 934, 936.

But the medical schools have been reproached with the statement that competition for fees has reduced them to the position of having to seek assistance from the funds of the hospitals. A keen critic of hospitals has asked: "I am going to put a boy, say, into the medical profession and I want to pay his fees. Why should I not pay his fees? Is it not a dreadful thing to be told that my boy is to be partly educated out of money which was given by the public for the sick poor?"[3] For anyone having this scruple a donation of £100 or so to the hospital funds would put the matter right. But looking at the question from the point of view I have mentioned I can see nothing dreadful in the position. Nor apparently did the chairman of the Medical Schools Committee, whose reply was: "You must bear in mind that the greater part of the higher education in England is eleemosynary."

Medical education, however, until the last few years has been an exception to the truth of this reply. Neither private benefaction nor public bounty has assisted it in London. Medical education is excluded from the list to which grants are made by the State. There is not, I believe, a single endowed chair in any medical school in London except the chair of physiology in University College and this has to be supplemented very largely to make the department effective.[4]

With regard to Question 2 in the "terms of reference" to the committee the answer given in the report is to the effect that the benefits arising out of the connexion between the hospitals and medical schools balance one another. Some of the witnesses, and to one's surprise medical as well as lay, who gave evidence before the committee held this view. It was asserted that the members of the hospital staffs make colossal fortunes and that the students are provided by the public with a "clinical laboratory," abounding in an enormous mass of "clinical material," for which they have nothing to pay and which otherwise would have to be provided in a hospital built and maintained by the medical school itself.

These are astounding statements. The advantages of hospitals to medical schools, of course, cannot be denied but the foregoing argument is none the less illusory. It would be even more to the point to say that the advantages conferred on the Bench and Bar by the High Courts of Justice and those conferred on the Courts of Justice by the Bench and Bar about balance one another; or that the benefits conferred on the army and navy by the country and those conferred on the country by the army and navy are mutual and equal.

It is surely grotesque to speak of the so-called "clinical material" in the light of an asset of the hospital in its account with the medical school—to liken this "clinical material" to a laboratory and, as if it were a chemical or physical laboratory, to pit its value against that of the services rendered to a hospital by medical skill and science The "clinical material" is not in the hospital to be bartered but to be relieved and cured. The reason of the existence of a hospital is to provide the best possible medical and surgical treatment for the sick poor. To this end there must be opportunities for clinical study on the part of those who are to combat disease. That proper use is made of these opportunities is "a matter of the very greatest importance to the public and to the poor. ...... It is an integral part of the mechanism for helping the sick poor."[5]

For years the hospitals had been the gainers by their affiliation with the schools, without having to pay a single farthing in return. Sir Isambard Owen, in his interesting oration last year, said that he had estimated that the existence of the medical schools virtually added no less than £50,000 a year to the charitable resources of London and that he had not been accused of exaggeration. But be that as it may, can one imagine such a state of indifference to the public weal, or such injustice to individuals, on the part of hospital managers as to suppose them capable of closing their doors to medical teaching or of attempting to make something for their hospitals out of the "clinical material" and the fees paid for clinical instruction?

Let us take the case of the fees paid by students attending hospitals supported by rates. What becomes of them? Students have to produce a certificate of having attended a three months' course of practical instruction at a hospital for infectious diseases; candidates for a diploma in public health, a certificate of having attended during three months the practice of such a hospital and of having done so with the opportunity of studying also the methods of administration. These requirements of the General Medical Council are met by the Metropolitan Asylums Board arranging for students' classes in the wards and providing a limited number of resident clinical assistantships. The clinical assistants get their board and lodging free, their services being considered as the equivalent. The fees paid for instruction go as to two-thirds of them to the senior medical officer and as to one-third to the Metropolitan Asylums Board to pay expenses for use of waiting-room, service of porter, printing notices and certificates, &c.

These hospitals being statute-ruled, the Asylums Board has to guard against the possible imputation that any part of the cost of medical education is charged to the rates; but it makes no tax on the use of the "clinical material." This arrangement surely is of itself a practical admission that it is those who do the teaching, not the hospital which masses the "clinical material," to whom the students and the schools are indebted.

Moreover, students go to a medical school, not because of the hospital, but because of the traditions and renown of the school, or because of the repute of this or that member of the staff. Take away from the hospital the distinction given to it by the school traditions and by the reputation of the medical and surgical staff and other teachers and the whole character and importance of the hospital would be changed.

I have said enough, I hope, to show that the report of the committee does less than justice to the medical schools by saying that the mutual benefits of the hospital and school "may be fairly set off the one against the other." But the committee further says: "The evidence satisfies us that the expenses incurred in hospitals with schools are generally in excess of those in hospitals without schools." Figures have been produced by Sir Henry Burdett to show that a medical school adds from 15 to 25 per cent. to the total cost per bed, as compared with the cost per bed in the hospitals without medical schools.[6] It came out, however, incidentally, in Sir Henry Burdett's own evidence before the committee, that a medical school was not invariably or necessarily associated with a higher rate of expenditure;[7] and Mr. Martin White in the *Times* of March 18th last has proved by a comprehensive tabular comparison of 13 Scotch, provincial, and London hospitals that the cost of management is not increased by medical schools but that many of the provincial and Scotch hospitals with medical schools are worked quite economically.

The report of the "Medical Schools Committee," besides replying to the three questions of reference, contains a *recommendation* as to moneys contributed to hospitals in future, and also some remarks on "*certain matters*" which came before it in the course of its inquiries and which it considered to be closely connected with the subjects of reference. The recommendation is:—

> [illegible] every case [illegible] arness that [illegible] o question [illegible] ontributed, [illegible]

As a result of this recommendation the General Council of the King's Fund has notified to the hospitals "that no grants will be made from the King's Fund as from and after Jan. 1st, 1906, to any hospitals which make payments to, or on account of, their medical schools out of general funds subscribed for the relief of the sick poor."[8]

As a matter of fact, the grants from the King's Fund to the hospitals with medical schools are but a very small part of the incomes of those hospitals, and the actual contributions to the schools out of the hospital funds form but a very small fraction of the expenditure of the hospitals. Thus in the case of the Middlesex Hospital the annual grant from the King's Fund is about £2000; the annual expenditure of the hospital is between £34,000 and £40,000, and the largest contribution made in one year out of the hospital funds towards the school is £965 8*s.* 11*d.*,[9] or less than 3 per cent. of the total expenditure. St. Mary's Hospital, with an annual expenditure of about £32,000, receives from the King's Fund about £2000 a year; the amount given to the school out of the general funds of the hospital in 1903 was £652.[10] St. Thomas's Hospital, with an annual expenditure of £62,000, does not receive a grant from the King's Fund every year. The grant in 1903 was £1800; the amount paid for or to the school out of the hospital funds was £1253 3*s.* 11*d.*,[11] or a little over 2 per cent. of the total expenditure.

The hospitals naturally wish to stand well with the King's Fund, and besides it is not only the loss of the grants from the King's Fund with which the hospitals which assist medical education out of their general funds are threatened, but the grants from the Hospital Sunday Fund—which in the case of the Middlesex Hospital and St. Mary's Hospital are somewhat larger than those from the King's Fund—will also, no doubt, be discontinued. At the last two annual meetings of the Metropolitan Hospital Sunday Fund resolutions were moved to the effect that no grants should be made to hospitals which contribute to the support of medical schools or laboratories from the general fund. Although on each occasion the resolution was withdrawn there is every reason to believe that at the next annual meeting the example set by the King's Fund will be followed by the Hospital Sunday Fund.

It is to be hoped, therefore, that those hospitals which have hitherto assisted their medical schools, and which do not feel justified in foregoing the grants from the King's Fund, will at once establish a "Medical School Fund" which can be used, at the discretion of the governing body of the hospital, for the requirements of its medical school; and also that those who are interested in securing the wider range of [illegible] al profession, [illegible] s of a hospital, [illegible] fund.

At the London Hospital a discretionary fund—that is, a fund to be used in part or in whole, at the discretion of the committee of management, for either hospital or school—has, in fact, already been opened, and within a week of its being started the amount transferred to it by the subscribers was more than twice the amount ever contributed to the school by the hospital.[12] There is no reason to doubt that similar generosity towards the other medical schools will be shown by the supporters of the other hospitals and that a response will be made to the claims and the needs of the schools if these needs are made widely known by the establishment of a separate and distinct fund.

The two "*certain matters*" as to which the "Medical Schools Committee" records its impressions are: (1) the broad line of distinction drawn between the studies of the first three years of the medical student's curriculum and those of the last two years; and (2) the effort now being made on the part of the University of London to concentrate the teaching of the preliminary and intermediate subjects of the medical student's curriculum, and as to which the committee expresses its "great satisfaction." The committee considers that "the earlier studies have no real relation with a hospital, and are therefore more properly to be pursued in an institution of a University character." Probably the committee inferred that the instruction to the Senate by the Statutory Commissioners of 1898 is in accord with the views of the whole of the 350-400 members of the Medical Faculty of the University. The committee, however, does not seem to have been informed that the average attendance at the meetings of the faculty is only 45; that only 48 members were present at the meeting when the reply of the faculty to the inquiries of the Senate of Feb. 19th, 1902, with regard to the proposed institute of medical sciences was passed; and that it is doubtful whether one-fifth of the members have ever attended a single meeting, or know what takes place at the meetings, of the Faculty.

It is the teaching of the preliminary science subjects *only* of which the medical schools ought to be relieved. This is the burthen which, especially since the coming into force in 1892 of the five years' curriculum, the schools have found it so difficult to bear—under which, in fact, they have broken down. These are the classes which, as arranged for medical students alone, have never paid, and which even at University College and King's College, where the departments of chemistry, physics, botany, and zoology are departments of the faculty of science as well as of that of medicine, are the most expensive and costly in the faculty of science. Even at these two colleges, in spite of endowments, grants from the Treasury for science teaching, and from the London County Council, it is extremely difficult to make these classes pay their way.[13]

Melbourne and Sydney, I am told, have had the same experience as the London colleges in regard to the unprofitableness of teaching preliminary sciences in medical schools. The proper relief from this burthen is to require that these courses of study should be taken and closed by passing an examination in them before the students are allowed to count the commencement of the medical curriculum.

Huxley, in a memorandum to the Senate of the London University, said "that the student ought to have acquired, as part of his general education, such knowledge of physics, chemistry, and elementary biology as is now demanded of him."[14] The General Medical Council and the two Royal Medical Colleges in London have approved in principle of these subjects being treated as matters of preliminary [illegible] an examination being passed in [illegible] in general education and before [illegible] cal studies proper. The mistake has been in allowing students to count any part of the time spent at a medical school before having passed the examination in preliminary science.

There would be no difficulty in students getting instruction in these subjects if the medical schools gave up teaching them. At present many intending medical students take out their courses in chemistry, physics, and biology before leaving school; most of the good secondary schools in England now have science departments and many have been inspected and found thoroughly efficient by the two Royal Colleges. In fact, the Colleges have given encouragement to secondary schools in this direction. Other places of instruction would soon become available. The Birkbeck Institution has a considerable reputation. At South Kensington and at various polytechnics and municipal institutions the teaching of the preliminary sciences is excellent in its way, and if not at the present moment quite suitable for medical students would no doubt soon become so if the teachers were encouraged to hold special courses for intending medical and dental students, and it would well pay them to do this. Examinations in these subjects could be held at the Examination Hall and elsewhere as now, or as an alternative a "leaving school certificate" might be accepted. For the preliminary scientific examination for the degrees of M.B. and B.S. of the University of London the classes at University College and King's College would still be available. Epsom

College also sends up many boys who pass this examination straight from school.

One important reason why the departments of chemistry and physics and biology have been so great a burden to the medical schools is that they have to be maintained in a thoroughly efficient state with a view to the teaching of those subjects up to the standard of the preliminary scientific examination of the University of London, and whilst the schools thereby incur considerable expense they do not receive the fees of all their students for the teaching of these subjects. This is due to the regulations of the University and of the Royal Colleges which permit of the courses of instruction in chemistry, physics, and biology being taken elsewhere than at a medical school. In a very considerable number of cases this permission is taken advantage of, so that when these students come to a medical school they claim exemption from the payment of the fees allotted to those subjects. This is not the case with anatomy and physiology, in which subjects all students must receive instruction at a medical school and pay the fees for these subjects.

Indeed, it is altogether different with regard to anatomy and physiology. They are the corner-stones of the foundation of scientific medicine and surgery and as such are not to be relegated to the limbo of the neglected or forgotten, after having been studied for two winters and a summer session. The dissecting rooms and the laboratories should be easy of access to the student throughout the whole period of studentship. A conference with the teacher of anatomy or physiology on a difficult or doubtful point is not infrequently of much assistance to a surgeon or physician of the hospital. Whatever may be the case with physiology, it will be quite impossible entirely to banish anatomy from the proximity of the schools attached to hospitals. Provision must always be made thereat for teaching surgical anatomy and for operations on the cadaver; and proper facilities to dissect must be given to senior men who are going up for such examinations as the Fellowship of the Royal College of Surgeons of England.

Those who advocate the concentration of teaching in these subjects at one or more centres away from the clinical schools affirm that "owing to the widening of the scientific basis of medicine and surgery and to the increasing attention given to the teaching of these scientific subjects it has become necessary to intrust these subjects to teachers exclusively occupied with them."[15] This statement contains in itself one of the strongest reasons for not allowing the teaching of anatomy and physiology to pass entirely under the control of pure anatomists and physiologists, as it would do at central schools presided over by professors in these subjects.

There is wisdom in providing for what is essential rather than for what is superfluous. It is possible to have a "basis" so wide as to be out of proportion to the structure reared upon it. It is possible to teach a subject as if the knowledge of it is the end in itself instead of a means to another end. In the teaching of physiology to medical students there has been a great tendency in this direction and the tendency would have become an actual reality had the examining bodies not kept a tight hand on the physiology examiners. But though the professors at centralised schools (who would be also the examiners) would themselves be exclusively occupied with their subject, the demonstrators, who would do the bulk of the teaching, would not be so any more than they now are but would take up the teaching, as they do at present, "as affording temporary occupation prior to entering upon other and more remunerative work elsewhere"—in other words, whilst waiting for hospital appointments. The demonstrators, however, would be under the disadvantage of having to spend the greater part of their time at the teaching centre, miles away from their hospitals, and would not be able to keep so closely in touch with clinical and pathological work as they do now, except at considerable expense and loss of time in travelling to and fro. The distance of the University at Kensington from the hospitals and from the residences of the teachers was considered by the late dean to be an explanation of the scanty attendances at the meetings of the medical faculty—few and far between as they are. What a great drawback, therefore, would the distance be to those who would daily have to go to and fro from one place of occupation to the other.

Concentration, too, has its disadvantages in the case of sciences which have to be learnt largely by the student's own manual efforts and have to be taught by direct demonstration to the individual student, as well as to classes, or by lectures. Moreover, all young men are not alike as to the the conditions under which they can work best. Many prefer to go to, and work better at, a medical school where there are but few students. As to the personal preference of the students themselves there are few, if any, amongst past and present students who are not glad that their own student-days arrived before any scheme of concentration could keep them for three years at a central institute away from the hospital of their selection.

It is said that the present system of teaching anatomy and physiology in 12 centres in London is at once "wasteful and inefficient." I shall be able, I think, to show that neither of these charges is justified. The objection, on the ground of inefficiency, to anatomy and physiology being taught by those who are looking not to teaching these subjects but to practising as surgeons and physicians as their principal work in life ought to be silenced by recalling the names of some of the past teachers. To mention only some few who are deceased, let us take for instance, Moxon and Hilton Fagge, who were demonstrators of anatomy at Guy's; or Kirkes, Savory, and Morrant Baker, who were teachers of physiology at St. Bartholomew's, or George Murray Humphry, the author of "The Human Skeleton" and of treatises on the "Limbs of Vertebrate Animals," &c. One of the best teachers of anatomy of his day was John Hilton, whose admirable dissections, copied in wax by the late Mr. Towne, are some of the chief attractions in the Guy's Hospital Museum and whose classical work on "Rest and Pain" is a monument of anatomical knowledge applied to the elucidation of obscure surgical affections. Sir Charles Bell—of whose work Müller, the great German physiologist, said: "The discovery of the circulation of the blood by Harvey and the discoveries of Sir Charles Bell on the nervous system are the two grandest discoveries that have ever been made in physiological science"—taught anatomy and physiology at a medical school at the same time that he was one of the surgeons of the Middlesex Hospital and was engaged in a considerable private practice as a consulting and operating surgeon. Towards the end of his London career Sir Charles Bell, whose pride, as he said, it ever was "to join the pursuits of science with practice," helped largely in establishing the medical school of the Middlesex Hospital and gave the first series of lectures on anatomy and physiology in that school. Then followed in the same chair Alexander Shaw, Bell's friend and assistant, a good anatomist and the author of some excellent treatises on surgery. Erasmus Wilson came after Shaw. His devotion to anatomical and physiological teaching and to writing "The Anatomist's Vade Mecum"—the popular text-book with students of that day—did not prevent him becoming the leading dermatologist of this country. Campbell De Morgan and Charles Moore, both surgeons to the Middlesex Hospital, have graven their names conspicuously into the history of the modern operative treatment of cancer by work they did whilst teaching anatomy at the same time. De Morgan for 19 years taught also physiology, and, conjointly with the elder Tomes, has left his name indelibly recorded in the Philosophical Transactions (1853) by their memoir on "The Structure and Development of Bone." Sir William Flower, the late conservator of the Hunterian and then of the Natural History Museums, in the earlier part of his career was assistant surgeon to, and teacher of practical anatomy at, the Middlesex Hospital. During this time he produced those excellent charts of the nervous system which have been of great assistance to many generations of students and laid down the foundation of his work on craniology. J. W. Hulke taught physiology and made an important contribution on the "Anatomy of the Retina." The late Arthur Hensman, who for several years demonstrated and lectured on anatomy at the Middlesex Hospital Medical School, was also surgeon to the throat and ear department of the hospital. He was an admirable draughtsman and a most successful teacher of anatomy.

This is no mean list of distinguished teachers at one school, and that one of the smaller ones, since 1835. It would be easy to mention many others, living as well as dead, who have brought renown to their respective schools in the double rôle of teacher of anatomy or physiology and of surgeon or physician to the hospital to which the school is attached.

The arrangements at the University of Cambridge are sometimes urged as an example in support of separating the place of the intermediate science teaching from the medical schools in connexion with the hospitals. But it is an example, in my opinion, not to be followed. Several Cambridge men, as it is, come to London for their anatomy and from what I hear are well pleased at doing so. At any rate, it is quite certain that medical undergraduates at an institute at South Kensington will not reap the advantages attending a residence at Oxford or [illegible] perhaps go some way to com[illegible]ing a medical school imme[illegible] [illegible] h exist in the provinces or in Scotland be compared with those in London. The amalgamation of a Sydenham College attached to the General Hospital, with the Queen's College in connexion with the Queen's Hospital, into a medical faculty of the University of Birmingham, or the combination of the separate hospitals and colleges of Liverpool into a University of Liverpool, is quite a different thing from concentrating the preliminary and intermediate science teaching of the separate schools of medicine in London.

---

[15] An appeal by the Senate for funds to endow an Institute of Medical Science.

In the case of the Durham undergraduates in medicine, their instruction in the preliminary sciences, as well as in anatomy and physiology, is given at Newcastle, in College buildings quite close to the Royal General Infirmary of Newcastle, which is the clinical hospital for the medical students of the University of Durham. It would be no less reasonable for the University of Durham to insist on the students of the medical faculty doing their anatomy and physiology and other science courses at Durham, which is 17 minutes by train from Newcastle, instead of at Newcastle, than it would be to require the London medical students to attend these courses, far away from their several hospitals, at South Kensington.

The fact is that London, from its vastness of area and of population, has, and requires, not one medical school but several. The London system differs, it is true, from that of Edinburgh and the provinces, as well as from that of Paris, Berlin, Vienna, and other continental cities. But the educational work it has accomplished, the well-trained practitioners it has turned out, its contributions to science, and its discoveries in diagnosis and treatment, have not been surpassed by those of any medical centre in the world. London has cause to be proud of her medical schools and in the interest of the hospitals, of the sick poor, and of the whole community she would do well to make a great effort to retain them.

Sir Edward Fry's Committee has amply pointed out how great are the benefits which the hospitals derive from the medical schools. This being also universally admitted, why take steps to concentrate the teaching of anatomy and physiology at a few centres when the probable result will be the deterioration, if not the actual extinction, even as places of clinical instruction, of at least three or four of the existing medical schools? It cannot be said that there is a preponderating desire on the part of the schools to be rid of the teaching of these subjects, because in the answers given in reply to a memorandum issued in 1901 by the Faculty of Medicine only four out of the 12 schools gave an unqualified assent to the concentration of anatomy and only five to that of physiology—and this in spite of their financial difficulties.

With regard to the scheme for establishing an Institute of Medical Sciences in South Kensington, it is interesting to recall how the idea of it came about. In the latter half of the "eighties" of last century the medical teachers in London took alarm at the decrease in the annual entries of medical students in London, so they joined University College and King's College in the demand for a teaching university which was to grant medical degrees on easy terms. In their anxiety they quite ignored the fact that, as to its medical faculty, the University of London was, and had always been, a teaching university; that by its Charters (Clause 37) it required evidence of study completed in accordance with regulations determined by the Chancellor, Vice-Chancellor, and Fellows; that the courses of study were laid down by the Senate after communications and conferences with colleges, professors, and examiners; and that these courses had to be taken at certain medical institutions recognised by the Senate. In other words, the University of London only admitted to its degrees in medicine and surgery such persons as had followed a curriculum of its own planning at institutions of its own approval. It thereby [illegible] examinations, and [illegible] constituent parts [illegible] uch a university is no less a teaching university than a boiler-maker living at Greenwich, whose capital is raised by syndicate and whose workshops are scattered at Erith, is any the less a boiler-maker because there is no hammering going on at his home premises. But the Gresham University scheme failed and in its stead the existing University of London was altered in 1898 by statutes. Still, there was no prospect of a London M.D. degree on terms to suit the general run of students, so a sop was thrown to Cerberus by the Statutory Commissioners, who reaffirmed the opinion of the Gresham University Commissioners (1894) that in certain groups of studies concentration ought to be effected; but they did not feel justified, however, in framing statutes to give effect to this opinion, because they found from representations made to them on behalf of the medical schools a want of such consensus of views as enabled them to do so. They therefore laid down the following instruction: "The Senate shall use its best endeavours whenever practicable to secure such common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres." These words are a part of the unfortunate and now notorious Statute No. 80—a statute which threw medical education in London into a state of distraction and has kept the teachers in a state of paralysing uncertainty ever since, and which, because it has been quoted by Sir Edward Fry's Committee "with great satisfaction," is on the eve of causing a considerable crisis.

The same statements which were used to advance the Gresham University as a teaching university granting easily attainable degrees are now being employed to bring Statute No. 80 into being in the form of the proposed Institute of Medical Sciences of the University of London. The institute, we are told, is necessary "for the improvement of medical teaching," to "restore London to the place it once held as a great centre of medical education," and to provide "a really great metropolitan school." The preliminary and intermediate subjects, it is said, are now being better taught in the provinces than in London with better apparatus and by better paid teachers, whilst competition between a great number of little schools is destroying medical education in London and injuring the London hospitals by a clear diversion of the funds.[16]

A fact is not created by affirming that it exists; but experience has shown that it is possible to go on saying the thing that is not so often that at length one actually comes to believe it to be the thing that is; and one may even go a step further and repeat it again and again, until one induces other people to believe it too. But the answer to the above fictitious statements is to be found in the evidence of the Principal of the University of London.[17] Sir Arthur Rucker told the "Medical Schools Committee" that "to compare the Medical Faculty of the University of London with the Med. [illegible] whatever is really to [illegible] different orders of mag[illegible] have more than one [illegible] dispensary. Here we ha[illegible] the principal ones are superior—at least equal—to those in any of the provincial towns."

The real origin of each of these movements (the Gresham University and the Institute) was the desire on the part of the London teachers to bring back, if possible, the medical students to London and, failing that, to be rid of the burdensome expenditure on the teaching of the earlier subjects of the curriculum. The position, however, is not that medical education in London has not been kept up to date but that the education in the provinces has made such great strides. In the beginning of the decline of the London entries it was cynically said "that the medical education of the country was year by year being injured by the drawing away from London of a large number of students who will go where they can get a degree, even if they cannot get the learning, and that that ought to be remedied at almost any cost."[18]

But provincial colleges have become provincial universities; local munificence has richly endowed them;

---

[16] Minutes of Evidence, Medical Schools Committee, Q. 834.

[17] Minutes of Evidence, Q. 112.

[18] Quoted in Lord Justice Fry's evidence before the (1888) Royal Commissioners, p. 99.

large hospitals and infirmaries are in their immediate neighbourhood, and thus all the requirements of a good medical school are combined. Rich in the fulness and variety of clinical material they have also ample funds for teaching the preliminary and ancillary sciences as well. These universities can now impart "the learning" as well as give "a degree" and the cynics therefore should no longer wonder that many students, loving country life and finding near at home the opportunity of getting *both* the professional training and the university degree, prefer to enter at the provincial universities. Nor is it surprising that their guardians or parents prefer sending them there rather than to London where they are far away from home influences and surrounded by the distractions and temptations of a great metropolis.

When will the London teachers realise that this condition of things has come to stay? A jealous coquette does not impair the charms of her rival by vainly striving to improve her own. Nor will any efforts to increase the attractions of the London medical teaching detract from those possessed by the provincial universities.

It is a matter for surprise that Sir Edward Fry's Committee should have gone so far beyond the "terms of reference" to them as to express satisfaction at the University of London scheme of concentration. It is a significant fact that the first questions of the Bishop of Stepney to the first witness who came before the committee distinctly postulate the advantages claimed for it. But one's surprise centres around the attitude of Sir Edward Fry. If we refer to the Blue Books of 1889 and 1894 and carefully peruse the evidence given by Lord Justice Fry in 1888 and by Sir Edward Fry in 1892 we find that though favourable to some inter-collegiate arrangement on the part of the smaller medical schools for teaching the subjects of the preliminary scientific examination of the University of London he was a strong and persistent opponent of placing the whole teaching in London under one control; that whilst he desired to maintain competition between the colleges in a university he expressed himself resolutely against the ill consequences of competition between universities; that, though in favour of a university controlling teaching by inspecting and reporting on teaching bodies, he was opposed to the University itself doing the teaching, and he quoted with approval and at great length from an address by Professor Chrystal of Edinburgh as to the drawbacks and dangers of the universities competing with the secondary schools for work which the schools can do as well as, or even better than, the universities can. It was not therefore to be expected that we should find Sir Edward Fry now viewing with satisfaction the proposal of the University of London to do all those things which ten years ago he thought so harmful—namely, to compete not only with the provincial universities, but with the medical schools which stand aloof from the concentration scheme, and with the secondary schools.

Now as to the charge of *wastefulness* which has been brought against the present system, more especially by the enthusiasts of the University of London Institute scheme. It was told in evidence to the "Medical Schools Committee" that in 1901 there were between 80 and 90 teachers for 1250 students of anatomy and physiology at the 11 medical schools of London, and that "the amount of money which was expended in salaries alone for the teaching of those subjects was more than £10,000 a year."[19]

If we compare these figures with those put forward by the University of London we find that the Senate is appealing to the public for £375,000 for building, equipping, and endowing the institute. (The estimate of the Committee of the Senate was £40,000 more—viz., £415,000.) The total annual cost of maintenance is estimated at £23,500. One hundred thousand pounds are to be spent on building and equipping the anatomical and physiological work-rooms. The salaries of the teachers of anatomy are set down at £5000 a year, those of the teachers of physiology at £5500 a year—i.e., £10,500 for the teachers of these two subjects. The proposed numbers of teachers of anatomy and physiology are nine professors and 24 assistant professors and demonstrators. The number of students to be provided for is 500. We see, therefore, that 33 teachers and £10,500 a year for salaries are the requirements by the University for 500 students. Now 33 teachers for 500 students are in the same proportion as 83 for 1250 students and £10,500 as salaries for teachers for 500 students are in the same proportion as £26,250 for the teachers of 1250 students; so that whilst the proportion of teachers is practically the same the amount paid in salaries for instructing 1250 students at the 11 separate medical schools is at the rate of £16.250 a year less than the salaries proposed to be paid for 500 students at the University institute. If to this be added the interest on the £100,000 sunk in buildings and equipment for the anatomical and physiological sections of the institute and the dead loss to the existing schools if buildings, plant, and ground space now covered by the present dissecting rooms and laboratories be thrown out of use, there is no difficulty in seeing that the charge of wastefulness recoils with greatly added force upon those who have made it.

The University of London as yet has neither the site for the buildings nor more than a fraction of the sum wanted to build and to endow. Even if both these needs were satisfied four or five years at least must elapse before the institute could be in working order; and if the existing medical schools, or some of them, should find it necessary to close their doors from and after 1906 when the decree of the council of the King's Fund comes into force medical education in London will be cast between the devil and the deep sea. The lot of the students will be like that of the children whose governess, thinking they ought to have a change of playthings, threw away the old toys before she could provide the new, with the result that the poor children were left with nothing to play with.

Any system which keeps a medical student away from the hospital for three years out of the five ought to be absolutely condemned. When the four-year curriculum was lengthened the intention was to add a year for clinical work but somehow the preliminary science teachers and the physiologists have been allowed to appropriate it. The final two years are consequently overladen; the students complain that too much of their time is given up to preliminary studies and too little to acquire a knowledge of the main work of their lives, and medical practitioners all over the country complain that the recently qualified assistants are very badly up in their practical work. A long experience as a lecturer and an examiner has convinced me that these complaints are well-founded.

In Germany, where the students commence to follow the "clinics" in the latter half of their second year, the authorities have become convinced that the teaching under the five years' system is not adequate to the needs of medical practice. Since 1900 loud voices have been raised pointing out that the education was too theoretical, and in 1902 the matter was taken up by the Prussian Minister of Education with the result that new regulations coming into force in 1906 require a sixth year which is to be spent entirely in clinical study and in holding hospital appointments. Hospitals with over 100 beds not previously connected with medical schools or universities are to form "academies" for this purpose.

With us in London the remedy is not exactly to add a sixth year to the medical curriculum but to relieve the curriculum of subjects which ought to be required as part of a liberal education before entrance on special medical studies. If the preliminary sciences were made to form part of school education the whole of the last three years or more could be devoted to clinical work and the other advanced medical studies; and the University of London could withdraw with grace from an attitude of rivalry with the secondary schools, and from the attempt to run a day-school at South Kensington for teaching medical undergraduates in their first year the elements of chemistry, physics, and biology.

There would still, however, be room for an institute of medical sciences in connexion with the University of London; for University courses of lectures on important subjects not taught elsewhere; and for post-graduate instruction in the higher grades of medical and non-medical subjects.

Courses of lectures and professorships might well be established in the subjects specified by the Statutory Commissioners—namely, (*a*) law, as a science and as a part of a liberal education; and (*b*) the theory, practice, and history of education. The philosophical study of the principles which underlie all systems of law would, as the Commissioners pointed out, be of great value not only to the professional lawyer but also to diplomatists, colonial governors, magistrates, and others who have to administer the law, whilst a course or courses of lectures on pedagogy would be of the greatest service to those engaged in secondary teaching, as well as to those in training to teach in elementary schools

---

[19] Minutes of Evidence, Q. 684.

The subjects which come within the purview of an institute of medical sciences in connexion with a university in which professorships and courses of lectures are wanted, are comparative anatomy and biology, biology of living organisms known to cause disease—i e, biology in relation to pathology, the more advanced branches of general physiology, physiological chemistry, and experimental psychology, tropical diseases, and the application of bacteriology to testing articles of food and to the micro parasitic diseases of domestic animals Medical men and others going to the colonies or to the tropics would be glad of some knowledge of Texas fever tsetse fly disease surra, and African horse sickness, &c, and those at home and abroad would like to know more about the organisms swarming around us and which affect the health of man and cause devastation amongst cattle But the most pressing need is adequate provision for scientific research and adequate accommodation for training future research workers Men are required who possess the technical skill necessary to make independent investigations in any part of the empire There are many important problems waiting to be unravelled by investigators efficiently trained

The field for research is wide enough and varied enough but the opportunities of learning technique and gaining skill therein are insufficient and in consequence the skilled labourers are few The University of London could do nothing of greater scientific usefulness nothing likely to be more beneficial to the public, nothing more becoming its own position and reputation as the greatest medical university, than found an institute of medical science for training research workers This might be done by the University alone or conjointly with the two Royal Medical Colleges, and either by means of State aid, and help from the Royal Society, or by means of funds raised through private liberality and patriotism There would thus come to be a supply of trained workers whose services would be available when required by Government or by commercial and industrial companies for original research work either abroad or at home The professors at the institute would conduct research work both of an independent and of a check or corroborating character, to them would no doubt be referred questions of difficulty, doubt or differences of opinion They might also initiate assist or coordinate researches conducted elsewhere with the consent and goodwill of the authorities of institutions as, for examples, at hospitals having specially favourable or extended fields for observation or study of special diseases Questions concerning tubercle, cancer infectious diseases, tropical diseases mental diseases and diseases of the general nervous system might thus be helped to a solution Such an institute for scientific research would be a crowning distinction to our University and would serve as a training ground and indirectly as a source of future income for many of the ablest and most scientific members of the profession, whilst the discoveries to which it would lead would be a means of improving the health and increasing the prosperity of those living in disease infested regions and would in this way prove a blessing to the whole empire and even to the world at large

The Lumleian Lectures

ON

NUTRITION AND MALNUTRITION.

Delivered before the Royal College of Physicians of London on March 28th and 30th and April 4th, 1905,

BY W. H ALLCHIN, M D LOND, F R S EDIN,

FELLOW AND CENSOR OF THE COLLEGE SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL

LECTURE III [1]

Delivered on April 4th

MR PRESIDENT AND GENTLEMEN —I have attempted to put before you in my previous lectures a general conception of what may be meant by nutrition and in so doing I have endeavoured to bring forward the most important of the recent work that has been done in connexion with the various processes which the function embraces It may be objected that in a course of lectures such as these and before such an audience as I have had the honour to address I was scarcely fulfilling my duty by devoting such a disproportionate share of my time to the consideration of the normal living I must confess, however that I am impenitent and that I have erred, if error it be, with intent For, believing as I do and as every physician I should think must do that however successful one may be by patient observation and inquiry in acquiring a knowledge of the clinical manifestations of disease and by due reasoning thereon arrive at what we call a diagnosis, or venture on a forecast and fortunate as we may be in devising means of relief and methods of treatment, there still must remain a constant desire to get deeper to the bottom of things and to form some idea however provisional however imaginary, of the actual changes that are taking place in the living elements themselves I do not believe that to indulge in such speculations provided always that they be held with proper reserve and subordinated to the ever accumulating facts that physiology and pathology teach, impairs in the slightest the physician s claim to be regarded as a practical man whilst that it confers an added interest to his work is indisputable The mere accumulation of facts so called often to be upset as more precise and extended observation becomes possible finds after all its chiefest value in furnishing the data whence may be ascertained the general principles of relationship which obtain amongst them and it is such principles which form the basis of our science and our art I must admit also that I was largely prompted to my choice of subject, apart from the great interest I have always taken in it, by the opportunity that these lectures offered of placing before you some of the results of the labours of that increasing band of workers at the problems of bio chemistry whence I feel assured physiology and pathology as well as rational therapeutics will receive the surest and most important assistance for their advancement Such results are not, in my opinion sufficiently often placed before those of us who are more actively concerned in the practice of our profession, are not made sufficiently accessible, not set forth with adequate indication of their bearing and significance even so far as scientific caution might permit [2] That I have occupied so much of my time as I have done in discussing the conditions and stages of nutrition appeared to me to be desirable and even necessary if I were to approach the subject of perverted nutrition on anything like a scientific basis as without a knowledge of the normal, imperfect though it be any conceptions as to the nature of the morbid states must be fundamentally vague and uncertain

I have considered nutrition as that series of changes which the ingesta undergo in the body to fit them for use by the living matter in the maintenance of its own integrity and

have been
summarised some of the later work done in connexion with the problems of nutrition

as the material from which energy is liberated. In the course of those changes the food-stuffs exhibit alternate disintegrations and integrations, finally to be excreted in a far simpler chemical condition than that in which they originally entered the body. In the first group of changes which comprise the function of digestion the proteids, carbohydrates, and fats to become capable of absorption into the blood undergo hydrolytic decomposition with the formation of products of less chemical complexity and this with but little loss of potential energy. During absorption by the intestinal epithelium some of these analytic changes are continued, more particularly by the proteids whilst the fats are in parts synthesised. Arrived at the liver a further synthesis takes place in the sugars and fats and perhaps also, though less probably, in the case of the proteids. Between this stage and the ultimate assimilation by the living protoplasm, these food-stuffs are in varying degree stored up in an insoluble form in different organs, liver, muscle, and adipose tissue especially, there to be made soluble by the same kind of agents with which they were dealt with in the process of digestion. Carried in the blood and lymph currents they may again be stored up, again to be converted into diffusible form. Among, also, these three groups of substances interchanges occur, whereby much of the starch foods is converted into fat, and proteids by decomposition set free a hexose group of atoms which may in its turn become fat. I pointed out that we had good reason to attribute these marvellous changes, comparable as they are to the ordinary chemical reactions which take place in our laboratories, but there only effected by reagents and temperatures that would be destructive of the living tissues, to the katalytic action of ferments which are themselves the specialised products of living matter. To bodies of this nature also it seems probable that the oxygen owes its ability to take part in the various syntheses and also to effect the katabolic changes which follow from oxidation; since at the body temperature the mere juxtaposition of oxygen and fat or sugar would be unable to bring about either oxygenation or oxidation results. Foremost among the capabilities of these wonderful enzymes are their adaptibility to the requirements made upon them and their reversibility of action, determined as these are by the conditions of the medium in which they are at work, on the presence or absence of the products of their activity and the degree of concentration of these products. Nor is it only outside the living cell that these ferment bodies effect their results; the intracellular processes whereby the protoplasmic molecule is enabled to synthesise the substance of its own composition from the comparatively simpler amido-acids and similar bodies, each variety of protoplasm manufacturing its own peculiar quality from, so to say, a common raw material presented alike to the nerve cell, to muscle fibre, and the secreting cell, all this I say, which is at the very centre of life itself, appears to be the resultant of ferment action. Although it is not contended that to express the problem in these terms is to offer a complete explanation of it, it is at least a step further towards the final solution and arguing from the known to the unknown, the hypothesis is not inconsistent with what is well ascertained and such a conception furnishes at least a coherent and intelligible basis from which to proceed further, provisional and tentative as it may be. Even more theoretical, though not wholly without grounds, is the reference of this vital activity of cells to ionic action, a view, be it observed, that really for the first time indicates the rôle that is played by the inorganic constituents of the ingesta and in showing the fundamental importance of these simple substances in the economy, links up the complex activities of the living cell with bodies that whilst suffering no chemical change are the carriers of that electrical energy which is more and more becoming recognised as the universal power.

This enumeration of the factors concerned in the maintenance of a normal nutrition suggests the directions in which we must look when endeavouring to comprehend the real nature of those perversions of the processes comprehended within the function which constitute disease. But it is seldom that a state of malnutrition is ever attributable to one cause only. Even when the primary error is comparatively simple and single the complicated relationships of the human organism are such that a disturbance, however slight at first, is liable so to interfere with the closely correlated functions of the body as to produce effects over a wide range and thus tend to obscure the real origin of the perversion.

MALNUTRITION DUE TO ERRORS IN DIET.

The first and the simplest causes of malnutrition are those connected with a deficiency of aliment leading to a condition of inanition. The pathology of this condition has long been known with tolerable accuracy due to the investigations of Voit. Careful observations have also been made not only upon animals placed under experimental conditions but also upon the several fasting men who have been before the public within recent years. Briefly the sum of these observations shows that there is a steady loss of body weight, after the first day or two the daily loss being fairly regular up to death—if the experiment be pushed so far. The total loss in a vigorous adult has been computed at four-tenths of the body weight but the young die much sooner and quickly succumb to the withdrawal of food. As is well known, the loss affects the different organs and tissues of the body to very different degrees, the heart and organs of the nervous system suffering least, indeed, the proteid nutrition of these structures is maintained at the expense of those of the systemic muscles and possibly of the glandular tissues, all of which with the fat are the first to be used up and suffer the greatest total loss. Investigation of the composition of the excreta shows that there is a steady breaking up of the body proteids, as may be measured by the urea, and that this goes on with a coincident destruction of the fats and to a less extent of the glycogen; when the last of the fats has been used up the amount of urea excreted is much increased since then the tissue proteids are the sole source of the body energy. "The carbon dioxide exhaled from the lungs during starvation continues to be given off in proportion to the weight of the body, to the work done, and in inverse proportion to the temperature of the environment" (Schäfer). At first the temperature of the fasting animal keeps about normal but later, as the metabolism is lessened in amount and the heat-governing centres are damaged from inanition, it falls and death takes place when the thermometer registers about 30° F. below the normal, which is incompatible with the continuance of the necessary protoplasmic interchanges.

In dealing with that form of malnutrition which is directly due to a deficient intake we have to remember that the average amount of food ingested by inhabitants of this country very considerably exceeds the quantity which is absolutely required to maintain metabolic equilibrium. And although the experiments of Chittenden previously alluded to may show that under certain selected conditions of satisfactory surroundings and regular exercise a metabolic equilibrium may be maintained on a diet which amounts but to a third or a half of what the average man eats with at the same time the performance of an average muscular work and the keeping of good bodily vigour it remains a question to be decided how far this reduction would be satisfactory under the ordinary conditions of civilised life. General experience would seem to be against it, and it is still to be shown that those individuals who live on such a restricted diet live longer or healthier or more vigorous lives than those whose diet is that of the ordinary person. So far as my observation goes they do not. Moreover, too, the element of habit requires to be considered, for this is apt to be most important in connexion with many of the circumstances of our being, and in such matters as the amount of food or of sleep that individuals find to be necessary for themselves it is of the greatest moment. At the same time certain general conditions should regulate the quantity of food taken, foremost among which are the age of the individual, or, perhaps one should say the period of life, of growth, maturity, or senility, and the character of the daily life so far as it manifests a lessened, average, or excessive energy. A neglect to observe these circumstances may contribute very actively to the establishment of malnutrition by failing to regulate the supply according to the demand and this not only in the normal state but also in the presence of existing disease where the food is not adapted to the needs and possibilities of the organism.

It is to be remembered also that the measure of malnutrition from insufficient—or assumedly insufficient—nourishment is not altogether to be estimated by the body weight, for there are not a few individuals whose weight is much below the average for their age and height and whose appearance is almost one of emaciation, but whose general well-being, as well as muscular and mental *activity* and powers of endurance, are quite up to the standard. So long as the individual remains in nitrogenous equilibrium and does not lose weight he cannot properly be regarded as underfed. Possibly our tables require revision in this respect. But what is more to the present purpose is that the intake of such persons may be by no means deficient and there are those who, feed them how we will, we are unable to add to their weight. On the other hand, that mere weight is not to be taken as a measure of nutrition is obvious, since the very obese are usually but poorly nourished, their nitrogenous tissue being weak and flabby and their capacity for exertion as also for resistance to morbific influences much diminished. That emaciation itself is not the sole index of malnutrition may be also seen by comparing the conditions presented by an advanced case of malignant disease or of certain grave nervous affections with the condition known as anorexia nervosa, when along with the extreme loss of weight the former are marked by muscular debility and general malnutrition in the fullest sense, whilst the last-named state is compatible with considerable muscular power and very often with a restlessness that is quite remarkable. Similarly, an increase in weight is not necessarily to be regarded as a sign of health, for whilst some people whose body weight is above the average owing to an excess of adipose tissue are active and energetic, hampered only by the impediment of bulk, others of like build are dull, lethargic, and quite incapable of exertion.

It is not very often that we are called upon to deal with actual starvation, with an intake, that is, which is obviously and gravely deficient. Those conditions of œsophageal stricture or of gastric disease which mechanically interfere with the necessary ingestion and are commonly due to malignant disease are less conclusive than those due to simple stricture, inasmuch as the morbid process may be responsible for the production of some material which influences prejudicially the metabolism of the tissues and thereby induces wasting apart from that due to deficient intake of nutriment. Whether this be so or not we frequently notice in such cases that the patient goes on, gradually it is true, getting worse, but yet without any very marked difference from day to day, until almost suddenly, without any very particular change in condition, he sinks and dies rapidly, having used up, as it were, the last available material or has ceased to secrete those enzymes without which the material is of no avail. The association of typhus and relapsing fever with famine is well known, as also the greater liability of phthisis in the underfed. Recovery from illness is also more difficult and protracted, and disease when present is likely to take a more serious course in such persons.

If now we turn to a deficiency in special ingredients of the food, too little, that is, of one or more of the requisite alimentary principles, it seems to be pretty clear that very serious states of malnutrition may be induced from this cause. It is generally supposed, and no doubt rightly, that the underfed person is less resistant to the ill-effects of pathogenetic organisms. Perhaps this may be explained in great part by the absence of those protective materials which in a perfectly normal state circulate in the blood current or may be readily developed therein, and among these there is some reason to include the proteids of the blood serum which, as I have said in my last lecture, are probably not destined to the nutrition of the proteid tissues, but which nevertheless depend for their maintenance in the blood on the proteid food.

There is another direction also through which a deficiency of proteid food may make itself felt. The influence of the alimentary principles of this class in stimulating metabolism is clearly recognised in the increased consumption of the adipose tissue on a meat diet, and the method of treating obesity in this manner is well known. They would seem to be a normal stimulus to protoplasmic metabolism, and that from this is to be explained the general impairment of vigour and enfeebled tone which are associated with a dietary which is deficient in proteid constituents. Exactly how this is brought about our present information does not allow us to state. But at least it must be recollected that the all needful ferments, not only those of the digestive secretions but those of the tissues themselves, to the activity of which we have seen reason to believe the manifestations of living tissue are so largely due, depend for their formation upon the nucleo-proteids of the cell, which depend again for their nutrition upon the intake.

In yet another, and possibly closely allied, manner the proteid ingesta appear to exert a very direct influence on nutrition apart from their constructive and fuel value. I have previously referred to the fact that the process of digestion is accompanied with a lymphocytosis and some recent observations by Dr. Galbraith[3] show that in pulmonary tuberculosis this lymphocytosis and also the hæmoglobin percentage are much increased by a raw meat diet. Now both the lymphocytes and the hæmoglobin play important parts in tissue nutrition, the former if in no other way by becoming agents for the transfer of fat from the intestinal epithelium into the commencement of the lacteals and the latter by the share it takes in bringing about the processes of oxidation. But since there is also found to be an increased nitrogen absorption and retention it is suggested that the lymphocytes give rise to some body which "links the nitrogen to the tissue cell."

In infants and very young children, more particularly among those fed upon many of the patent foods, a very distinct failure in nutrition is to be recognised as being due to proteid starvation, and that is in most cases quickly recovered from on an adjustment of the diet and the administration of a larger proportion of nitrogenous aliment. Whether, as is most probable, the proteid deficiency first of all affects the blood-forming tissues, the red marrow and the adenoid structures, cannot, so far as I know, be precisely affirmed, but certain it is that the blood in such children as I am referring to is of a deteriorated character and they exhibit the general features of anæmia, among which listlessness and obvious want of tone and energy are perhaps the most striking. Certain cutaneous rashes are also of frequent occurrence. Although such children are obviously ailing they need not by any means be thin; on the contrary, they are frequently fatter and of heavier weight than the average. But their condition is best expressed by the term "flabby" and the adipose tissues generally are hydræmic, a state that has been called "hydroplasmic obesity." It is clear, therefore, that for various reasons a deficiency of proteid ingesta—and included therein the all-important nucleo-proteids—will prejudicially affect the nutrition of the organism.

It is seldom, if ever, that we meet with a condition of malnutrition which can be attributed to a deficiency of carbohydrate ingesta but in respect to fats the case is different. Here, again, it is in the growing period of life, and particularly in the earliest months, that a lack of fats is the cause of a serious perversion of nutrition. After the conclusive results of the feeding of rickety lion cubs which had been brought up on lean meat there can be no doubt that a deficiency of fat in the dietary of children is the essential cause of rickets. Most probably the condition is intensified by a want of proteids and, of course, by a want of lime salts, but these two constituents of a proper aliment are not nearly so often lacking as fat is in the numerous prepared foods upon which rickety children have almost invariably been brought up. Probably no such complete illustration could be given of the direct relation of meat-nutrition to a defect in the ingesta as is the case of the connexion of rickets with a fat deficiency, for it is so clearly demonstrated by the relief of the morbid state by an improvement in the dietary. In speaking of rickets it must not, of course, be forgotten that the bone changes constitute but a part of the disease, for the muscles, the nervous centres, the mucous membranes, the blood, and, indeed, the tissues generally, exhibit in varying degrees structural imperfections and functional defects. A more particular relationship of deficiency of fat in the food has been thought by some to obtain with certain nervous diseases more particularly as occurring in infancy, or at least that the foundations of the affections were laid then, but of this I have been able to obtain no precise information. A deficiency of fat has also been associated by some with an impaired power of resistance to microbic invasion, particularly of the bacillus tuberculosis. Until recently scurvy has been almost universally regarded as a disease due to deficiency of certain food constituents and by many these were supposed to be the potash salts of citric, malic, and tartaric acid. Recent observations have, however, rendered it very doubtful whether this is really the essential cause of the malad[illegible] tion of fre[illegible] salts goes [illegible] assist materially in its cure when it is established, though the salts given as *such are ineffectual.*

Passing now to malnutrition, the result of over-feeding, the question at once arises, At what point can this condition be said to occur? As provocative of disease it certainly cannot be supposed to exist when any excess, however slight, is taken over and above what is exactly required to balance the expenditure of material. Such a view would allow no margin for reserve, the presence of which in the body is a necessity to meet the fluctuating and irregular demands of ordinary living. Although it is notorious that a large number of persons daily consume more food than is physiologically required, even with such overplus as may be regarded as primary or necessary reserve, it is difficult to regard this as over-feeding, especially if a fair amount of muscular exercise be taken, if the weight remains uniform, and there is no evidence of disease. The effects of an excessive diet upon healthy adults living ordinary lives have been studied experimentally by Dr. F. W. Goodbody, Dr. N. D. Bardswell, and Mr. J. E. Chapman[4] and with very interesting results. A careful balance-sheet was drawn up of the ingesta and excreta of each of a series of normal individuals subsisting on an ordinary diet such as they were accustomed to and upon which they maintained good health. When this was obtained the quantity of food was very much increased, in some cases the amount of the alimentary constituents being doubled or nearly so, and another balance-sheet was prepared in the altered circumstances. One striking result was the considerable increase in body weight, notwithstanding that the forced feeding could only be continued for a very few days, since in all cases, though in somewhat varying degree, the change in diet set up a marked disturbance in the general health. The appetite became lost, a sense of weight at the epigastrium was experienced with distension of the abdomen, and diarrhœa set in with colicky pains. The gain in weight was lost in the course of a week after the forced feeding was discontinued, but it was several weeks before the individuals regained their health. The quantity of urine passed on the excessive diet was increased and very much in proportion to the increased intake of fluids and at the same time the specific gravity was much increased. The quantity of nitrogen in the form of urea, uric acid, and ammonia, and the amount of inorganic salts were much in excess of the normal, but the nitrogen in the fæces was not increased, showing that the proteids had been digested and absorbed and excreted by the ordinary channel and not simply passed through the alimentary canal. But this was not the case with the fat which was largely in excess in the stools, offering thus a marked contrast to the proteid intake. A similar inquiry was undertaken by Dr. W. Hale White and Dr. E. I. Spriggs,[5] but in this case the subject was a woman who had neglected her meals under the stress of anxiety and sleeplessness and though 38 years of age only weighed 6 stones 2 pounds. The diet upon which she was placed was nearly three times in amount that of a normal individual and this was perfectly well tolerated without any of the discomforts and symptoms manifested in the previously mentioned cases. She gained weight considerably—13·256 kilogrammes in 56 days—and the analysis of the fæces showed that she retained 96 per cent. of the ingested fat. In comparing the beneficial result of an excessive dietary observed in this case with the less satisfactory consequences which characterised the experiments of Dr. Goodbody and his colleagues it must be noted that the woman started on the feeding from, so to say, a lower nutritive level than did the male subjects who were healthy. That the general condition of the individual on commencing a largely increased intake does affect the character of the result is further illustrated by the observations made by Dr. Goodbody and his colleagues on metabolism in phthisis.[6] Among the conclusions they arrived at were, that "while comparatively large diets were well borne by those much below their weight, they were not so well tolerated by, nor did they give such satisfactory results in, patients up to weight and with arrested disease."

---

[3] The Practitioner, February, 1905.

Very definite consequences are likely to ensue from an excessive ingestion of the individual alimentary principles. When this takes the form of a much increased proteid intake there is found to be a corresponding increase in the nitrogenous excreta chiefly in the form of urea and some increase may also occur in the amount of the other products of proteid cleavage. Of these, most attention has been directed to uric acid in consequence of the relationship of this substance to the complex condition known as gout. Since, however, it has become known that this material is an excretion product of nuclein metabolism derived from cellular tissues, especially leucocytes and gland cells, and only partly and in uncertain quantity from the proteid intake, its interest in relation to the food is of less moment. With further knowledge, which is much to be desired, concerning other members of the purin[7] group such as xanthin, hypoxanthin, guanin, &c., as well as of the derivatives of proteid decomposition other than urea, such as creatin, creatinin, the amido-acids, &c., we may hope for a clearer conception of the inter-relations of these bodies and their connexion with morbid states, whether as causes or results. Meanwhile, however, it is certain that no ratio of production exists between urea and uric acid and their formation and consequent excretion in all probability are quite independent. When the excessive proteid ingestion is accompanied by a diminution in the amount of fats and carbohydrates there is a general increase in tissue metabolism as seen by the increased consumption of the body fat. How this is brought about is far from certain.

Although, no doubt, fat makes fat, this is only true to a certain extent, for a very large fat intake is followed by a considerable increase of fat in the stools, in great part in the form of fatty acids, showing that though a splitting has taken place in the alimentary canal the absorption has been deficient. The experiments before referred to on metabolism in phthisis show, however, that even when the temperature of the patients was raised the fat assimilation with a much increased ingestion was very complete, over 96 per cent. being absorbed. The carbohydrate intake, however large, appears to be capable of absorption, and provided an indigestion be not established the greater part is stored as fat. When the excess is taken in the form of sugar, and perhaps also sometimes as carbohydrate, the amount may be more than can be converted into glycogen or fat and is excreted at once as sugar constituting the condition of alimentary glycosuria.

MALNUTRITION DUE TO MALDIGESTION AND MALABSORPTION.

Having thus dealt with the nutritional defects consequent on improprieties in the quantity and quality of the ingesta we have now to consider such forms of malnutrition as may be referred to disturbances of those processes which are concerned with dealing with the food, with, in fact, maldigestion. I need do no more on this occasion than refer for one moment to the far too frequent misapplication of the terms indigestion or dyspepsia, with, as I believe, the effect of adding thereby to the confusion which already attends a difficult subject. Used in reference to this or that group of symptoms which thus tend to be raised to the position of separate diseases it is too often forgotten that such symptoms are but the expression of some flaw or flaws in the performance of one or other phase of the entire process of digestion, or it may be of the subsequent stages in the progress of the ingesta, to the recognition of which every effort of the clinical observer should be directed and without which treatment becomes wholly empirical and fanciful.

The various factors concerned in the carrying out of the digestive function offer almost innumerable opportunities for its mal-performance. Thus, apart from the structural integrity of the organs concerned, which, of course, is a fundamental requisite, there must be a sufficiency in the quantity and the composition of the several secretions, together with a proper tonicity and activity of the gastro-intestinal musculature, whereby the different stages of the digestive act are enabled to take place without either undue delay or undue haste. As a most necessary preliminary also must be an effective mastication for which sound teeth are essential. Now the motor and secretory phases of digestion are directly controlled by the nervous system, the healthy condition of which becomes another requisite. That the chemical stages of digestion should be completely carried out in the stomach and intestines it is needful that the digestive products so soon as formed should be removed lest their accumulation arrest further action of the ferments, hence the ready absorption of these digesta becomes a necessity. For the efficient occurrence of this, as indeed for a normal motility and secretory performance, a proper blood-supply is postulated, which introduces another source of possible defect. Since the extent and character of the chemical changes in the alimentary tract are so largely conditioned by the nature of the food that is present, the composition and quantity of the secretions varying with the digestive requirements of the ailment, it is impossible to exclude the ingesta in this purview of the whole process, apart from any prejudicial effect they may have in their indigestible or even toxic qualities. Concerning the mutual effect of the coincident digestion of numerous alimentary principles at different stages of the process we know but little, though it must be of importance in bringing about the final result, whether this be normal or the reverse. Pawlow has shown in some cases that a beneficial influence is exerted by the presence of certain ingredients of the food upon the digestion of others, but it is equally sure that a harmful influence is exerted in others. The richer quality of the gastric juice which is secreted when bread is mixed with the meat and the inhibitory effect of fat on proteid digestion are comparatively simple illustrations of this statement. The progressive interdependence of the successive phases of digestion has already been dwelt upon, but that the interference with one stage is hence not only harmful in itself but further harmful in the interference with subsequent stages may again be emphasised. Nor does this complete the category of opportunities for maldigestion to occur. We know very little about the bacterial action on the intestinal contents but sufficient to show that some of their action is beneficial if not absolutely necessary, whilst on the other hand a large mass of evidence indicates that many conditions of intestinal indigestion are due to micro-organisms. Lastly, there is to be reckoned with the excretory function of the gastro-intestinal mucosa. That various substances may be excreted from the blood into the alimentary canal, urea, morphine, &c., is known but to what extent this occurs in health, if it do so at all, or what the effect may be, we do not know, but it is at least a possible if not a probable source of digestive disturbance. In such a complexity of conditions it is hard to trace the primary fault but it should be accomplished if we are to arrive at the real nature of any case of indigestion or of a malnutrition which is referable to digestive disturbance. Undoubtedly the simplest, as they are the most obvious, cases in which an error in digestion is responsible for malnutrition are to be found in those patients who are suffering from an exclusion of one or other of the digestive secretions from the alimentary canal. Such a condition occurs in those diffuse carcinomatous infiltrations of the stomach [illegible] by an occlusion of the [illegible] reaching the duodenum. [illegible] general malnutrition in such cases are notorious, more particularly in the pancreatic affection; and when the obstruction in the duct is non-malignant in nature the result is plainly due to the grave disturbance in the digestive process without the added harmful influence that characterises malignancy.

[6] Transactions of the Royal Medical and Chirurgical Society, vol. lxxxiv., 1902.

[7] Purin bodies are those containing a nucleus C_3N_4 termed by E Fischer "purin." They are closely connected with the nucleins from which in the body they are mainly derived. The best known of the group is uric acid.

Of the effect of the absence of individual constituents of the digestive juices we know but very little. The condition within this category most familiar to us is the deficiency of hydrochloric acid secretion in the stomach with the marked amelioration of the resulting dyspepsia that follows the artificial administration of the acid. But in this connexion it may be observed that defects in gastric digestion are far less likely to affect the general nutrition than are perversions of the processes that should take place in the intestine, for these are the most important in relation to the digestion of the food and appear to be able to compensate to a very considerable extent for deficiencies higher up in the canal. It is true that gastric indigestion is responsible for many [illegible] but apart from a malig[illegible]ith a very fair standard of [illegible]ay be estimated by body-weight and by bodily and mental activity.

Imperfections in the motor activities of the digestive process may lead to malnutrition if sufficiently long-continued but only indirectly. Thus a constant diarrhœa or [illegible] from any serious [illegible] chemical changes [illegible]sting and general functional impairment, but this effect is clearly due to the too rapid ejection from the canal of the ingesta without their having the opportunity of being either fully digested or absorbed and brings the result akin to that which follows from an insufficient administration of nutriment. When the error in gastro-intestinal motility is of the opposite character and the propulsion of the gastric contents into the duodenum is unduly delayed or the waste residue in the colon is unduly retained the materials are apt to undergo abnormal decompositions and by the production of toxic substances interfere with the health of the individual. But here, again, it is less a condition of malnutrition that commonly becomes established but rather a number of symptoms of a more or less discomforting character with which the general nutrition and bodily ability may be well maintained. Such lesions of the intestinal mucosa or of the lacteal vessels and lymphatic glands which drain that membrane as cause an extensive structural change are likely to lead to serious malnutrition for obvious reasons. A widespread denudation of the epithelium of the mucous surface of the small intestine and atrophy of the membrane were long ago described by Nothnagel as the commonest cause of marasmus of infancy and early childhood and the persistent wasting with loss of energy sometimes seen after typhoid fever is attributable to a similar cause.

MALNUTRITION DUE TO PERVERTED METABOLISM.

As might be expected, the more profound disturbances of nutrition, and those most clinically interesting and pathologically obscure, are those connected with perversion of the synthetic stages of metabolism. It is here, also, that is to be sought the real explanation of those conditions which are primarily to be referred to a faulty dietary or a maldigestion. For however important defects in the several factors of nutrition as just enumerated may be in the production of malnutrition they can seldom be regarded as the essential cause. If for no further reason, it might be pointed out that deficiencies in quantity or quality of the food-supply or imperfections in the digestion of the food may take place to a considerable extent and yet be unaccompanied by any such change in bodily condition as can be termed malnutrition, whilst, on the other hand, very grave malnutrition can occur with no apparent perversion of either the food-supply or of its digestion or absorption, as witness the cases of diabetes mellitus, the malignant cachexia when the new growth is unconnected with the alimentary tract, or extreme obesity. It is not until the essential factor of nutrition is involved that any serious deterioration in the function can really be said to occur. Now this essential factor we have seen to be ferment activity and the actual causation of malnutrition is to be found in such circumstances as prejudicially modify enzyme action.

I pointed out in my last lecture how dependent these bodies are for their activity and, what is even more important, the particular kind of their activity upon the nature of their surroundings. It is only within a comparatively narrow range of temperature that they will act, each having its own optimum point and all being destroyed at or about 100° C., though in a perfectly dry heat capable of maintaining their power to a much higher temperature. It is not, however, that such temperatures as are met with in the living body affect to any appreciable extent the enzyme action and can scarcely be considered as in any way responsible for defective action and consequent malnutrition.

Another condition upon which the very production of the enzyme or its precursor appears to depend in many cases is a due supply to the cell protoplasm of certain ingredients chiefly nitrogenous in character. Long ago Schiff showed that the secretion of pepsin depended on the ingestion into the stomach or injection into the blood of such material as solutions of peptones, or gelatin, or meat extracts, or even of dextrin. The relation of secretin to trypsinogen formation is an example of this dependence. Though I am not aware of any work that could show a defective ferment action and an impaired nutrition as being due to such a cause as this, [illegible]e a possibility that should [illegible] these "stimulants to enzyme secretion," as they may be called, are probably very numerous and differ to some extent for each ferment.

I pointed out in my last lecture also the very important discovery of Croft Hill that the direction of intracellular ferment action, whether synthetic or anabolic, or analytic or katabolic, was in great measure conditioned by the degree of concentration of the products respectively of anabolism and katabolism, and it is easy to see with what facility this degree of concentration may be affected by the inhibition or exudation of ever so without it. Among such bodies, it will be remembered, are to be ranked the ferments. But this is not all. Loeb found that the unfertilised ova that had proceeded to a certain degree of segmentation might by a careful addition of certain salts to the sea water in which they were situated develop a further segmentation and ultimately proceed to the formation of a perfect embryo, such as would result from impregnation and this without the spermatozoon—a veritable parthenogenesis. Differences in the time occupied alone seemed to distinguish this artificial from the natural course. As I have before said, the effects of these simple saline solutions, whether in favouring segmentation or in arresting it, he attributed to ionic action, and whether the spermatozoon conveys to the segmenting ovum a ferment or ferments it is to the ions which it carries that he ascribes its effects. Whilst not claiming that these experiments disclose the origin of life they at least show that, given the living ovum, its future development may be made to depend on the artificial adjustment of its environment. But the point is that without such artificial influence or without impregnation the mature ovum will die; fertilisation therefore, whether natural or artificial, prolongs its life. If, then, it is possible by the application of certain electrolytes to avert from a living ovum what may be termed its natural death, similarly to avert the degeneration and death of the tissue cells of higher organisms may be looked upon no longer as a hopeless quest.

GENERAL CYSTIC DISEASE OF THE KIDNEYS IN BROTHER AND SISTER; NEPHRECTOMY.

BY EDGAR L. COLLIS, B.A., M.B. OXON., M.R.C.S. ENG.,
HONORARY SURGEON TO THE CORBETT HOSPITAL, STOURBRIDGE;
AND
JOHN T. HEWETSON, M.D. EDIN., M.CH. BHAM., F.R.C.S. ENG.,
SURGICAL CURATOR AT THE PATHOLOGICAL MUSEUM, UNIVERSITY OF BIRMINGHAM.

GENERAL cystic disease of the kidney in the adult is probably less rare than we suppose. The following two cases, however, are worthy of publication, partly because of the fact that the patients were brother and sister, partly because of the difficulty we still have in recognising the disease, and partly because of the value it may be to others in the treatment of similar cases in the future.

CASE 1.—The patient, a female, aged 38 years, single, a district nurse, was admitted to the General Hospital, Birmingham, on Sept. 1st, 1901, complaining of abdominal pain and frequency of micturition. There was no evidence of tuberculosis or syphilis in the family history. In 1893 the patient was seized with severe pain in the left loin which lasted a few days. The pain was accompanied by frequency of micturition, the passage of dark muddy urine, and of three small urinary calculi, the largest of which was of the size of half a hazel nut. During the last five years she had been subject to intense attacks of migraine which lasted one or two days and completely incapacitated her from work. These attacks occurred at first during menstruation only but latterly they had occurred several times in the month. For the last three years she had, for economical reasons, lived on almost a starvation diet and a few months ago she experienced a very keen domestic disappointment. In these circumstances she rapidly lost weight and suffered more frequently from headaches. It was whilst in this lowered physical condition that the present attack supervened. About a month prior to admission to hospital under the care of Mr. H. G. Barling she began to suffer from frequency of micturition. A week before she was seized with acute cutting pain in the left loin which radiated down the left leg. The pain remained agonising for two days and then somewhat abated. The frequency of micturition became intensified during the attack of pain.

On examination a large mass was found projecting from the left costal margin and occupying part of the left hypochondriac, left lumbar, epigastric, and umbilical regions. Its lower end reached as low as the level of the anterior superior iliac spine and anteriorly to within two inches of the umbilicus. The mass measured nine and a half inches in length and five and a half inches in breadth. Its surface was very irregular; its shape was reniform; though generally giving the impression of a firm, solid mass, there were distinct areas of fluctuation scattered about its surface. It was moderately moveable and could be projected backwards and made to bulge in the loin. It moved slightly with respiration and was somewhat tender on manipulation. On percussion the descending colon appeared to be in front of the tumour. The right kidney could be readily palpated and appeared to be about twice its normal size.

The urine on Sept. 22nd, 1901, had the following characters. Quantity per diem, 24 ounces; specific gravity, 1026; reaction, acid; there was a faint haze of albumin. Microscopically it showed a few red blood corpuscles but no pus cells or tube casts. On the 26th: quantity of urine per diem, 48 ounces; specific gravity, 1015; reaction alkaline; a faint haze of albumin. Microscopically there were triple phosphate and oxalate of lime crystals in scant numbers; no blood cells, pus cells, or tube casts were present. The blood gave a leucocyte count of 8000 per cubic millimetre and films that were characteristic of a mild form of secondary anæmia. The liver was not enlarged. There was no obvious cardiac hypertrophy. The aortic second sound was slightly accentuated, the arterial tension was normal, and there was no vascular sclerosis. There was no œdema of the feet or legs and a careful vaginal bimanual and rectal bimanual examination revealed nothing abnormal in the pelvis. The bowels were regular. In considering the diagnosis it was felt that the result of the vaginal and rectal examination quite excluded the uterus and ovaries as a possible source of origin of the mass and that the blood examination practically dismissed the spleen. We were thus universally led by the shape, position, and associated symptoms of the tumour to regard it as of renal origin. Cystic degeneration was mentioned by virtue of the irregularity of outline and apparently bilateral enlargement, but the prevailing opinion was that it was either a hydronephrosis or a pyonephrosis arising probably from a calculus. The history of previous calculi and the absence of tubercle in the family tended to confirm this view. The normal leucocyte count, temperature, and pulse-rate were points against its being a pyonephrosis. Mr. Barling himself regarded the case as one of hydronephrosis.

Operation was performed on Oct. 7th, 1901. The usual oblique lumbar incision was made. The tumour was found to be an enormously enlarged kidney in a state of advanced cystic degeneration. On aspirating, some of the fluid it was found to be of a dirty amber colour suggestive of urine containing pus. This fact, together with the advanced stage of degeneration, induced Mr. Barling to perform nephrectomy. The operation was successfully completed without wounding the peritoneum or damaging the capsule of the tumour. The artery, vein, and ureter of the kidney were ligatured separately by catgut, a large drainage-tube was inserted, and the wound was stitched up. The patient left the table in a good condition without manifesting any marked evidence of shock. The fluid drawn off from several of the larger cysts during operation contained urea.

Pathological appearances.—The kidney removed was a magnificent specimen of general cystic disease, weighing 2 pounds 14 ounces (1300 grammes) and measuring in length nine inches (22·5 centimetres), in breadth five inches (12·5 centimetres), and in thickness three and a half inches (7·75 centimetres). The kidney was studded on the surface with thin-walled cysts varying in size from that of a pea to that of a Jaffa orange. So thin were the walls of some of the cysts and so large in size that on holding the organ up to the light it was possible to see from one side of the kidney to the other. The larger cysts showed evidence of multilocular development. The capsule of the kidney was preserved intact and was purposely stripped from one-half of the tumour in order to show that the cysts were in the kidney tissue and not merely subcapsular. At various points of the surface the capsule presented thickened cicatricial areas, due probably to the rupturing of cysts and subsequent inflammatory reaction. The contents of the cysts show all gradations from clear, serous-looking fluid to dark brown gelatinous substance. The ureter and pelvis of the kidney showed a moderate degree of thickening. There were, however, no dilatation, no evidence of calculi, and no congenital abnormality visible to the naked eye. The renal artery and vein were considerably hypertrophied.

Microscopical sections of the kidney showed that the cysts were for the most part lined with a single layer of epithelium which varied from simple squamous to columnar cells, the greater number being lined by a low cubical type of cell A few of the cysts were entirely devoid of epithelial lining Outside the epithelial lining was a more or less condensed part of the interstitial connective tissue of the kidney The contents of each cyst were generally homogeneous, staining a brilliant yellow by van Gieson s stain A few of the cysts contained catarrhal cells and polynuclear leucocytes scattered amongst the homogeneous substance There appeared to be every gradation in size from a healthy kidney tubule to the largest cysts and there were large numbers of what resembled normal *and slightly dilated tubules* which contained a homogeneous substance identical with that found in the larger cysts Many of the kidney tubules showed catarrhal changes similar in all respects to those seen in interstitial nephritis There were, however, large tracts of kidney tissue situated between adjacent cysts in which the tubules appeared to be almost normal and, on the other hand there were similar tracts of loose fibrous tissue in which kidney tubules were quite absent One of the most striking changes in the kidney tissue was the widespread destruction of Malpighian bodies This appeared to have resulted from a process of thrombosis beginning in either the efferent or afferent vessels which was followed by round celled infiltration Finally the body probably shrivelled and was replaced by a knot of fibrous tissue arranged in a concentric manner The interstitial tissue of the kidney was more or less increased everywhere and there were large areas of round celled infiltration indicative of inflammatory reaction The walls of the blood vessels of the kidney were enormously hypertrophied

After history —The wound healed by primary union and the convalescence was uninterrupted On examining the abdomen *on Oct 12th, five days after* the operation it was found that the right kidney had rapidly increased in size and could now be felt to be irregular and of firm consistency The daily amount of urine passed began to increase a few days after operation and the urine maintained a good specific gravity Towards the end of the patient's sojourn in hospital the amount of urine diminished until it reached a fair average standard The patient left hospital on Nov 2nd with a perfectly sound wound and one kidney enlarged to about four times the normal size,

to general

performing

On her dismissal from hospital she was advised to take a diet and to live a life similar to those suitable for a person suffering from interstitial nephritis Most of us however, including Mr Barling, took a very gloomy view of her expectation of life which we put down at something like 12 months The after history, therefore is one of considerable interest For 12 months she remained under the care of Dr T M Tibbetts of Cradley for whom she nursed Writing to one of us on Sept 6th, 1903 Dr Tibbetts says of her "For some months after her operation *she was as would be* expected weaker and paler than usual and there was a certain flabbiness and muddiness of complexion with puffing

, but her strength

ached almost the

— not quite so good

as formerly She has been nursing cases for some months now and has never complained to me of anything unusual in the urinary functions and she has not had an attack of migraine since her operation During the last month the patient has gone to take a permanent post as matron of a residential home One of us has kept in communication with this patient during the whole of her stay there and has received samples of her urine from time to time

On Sept 12th the patient reported herself as feeling perfectly well and able to perform her duties without the slightest discomfort The urine at this time had the following characters colour pale straw, reaction slightly alkaline, specific gravity 1010, amount 80 ounces per diem, albumin present, 0 75 per cent, urea 1 2 per cent, deposit very small on standing consisting of pus cells and epithelial cells, no crystals, tube casts, or blood cells being present *On Oct* 31st a 24 hours specimen was examined with the following result colour, of a hazy straw reaction, neutral, volume, 3800 cubic centimetres, specific gravity, 1010, albumin, 0 75 per cent, urea, 26 grammes, uric acid, five grammes no creatinin, no hippuric acid Microscopically there were pus cells in considerable quantities, red blood corpuscles in scant numbers, epithelial cells, round cubical, and squamous, and uric acid crystals in scant numbers

On Jan 22nd, 1904, the patient, being in the Midlands, consulted one of us just to report herself She looked robust and well, having put on about two stones in weight since her operation She was slightly anæmic and had a little palpitation after going upstairs Since her operation two years and four months ago she had experienced three mild head aches, each lasting one day only Her feet occasionally became swollen at night time but there was no œdema of *the legs or ankles at the time of consultation Her heart* was apparently a little hypertrophied, the apex beat being best felt in the nipple line in the fifth interspace the upper part of the left margin reaching as high as the second left cartilage The aortic second sound was distinctly accentuated and the arterial tension appeared to be increased but there was little or no arterial sclerosis The ocular fundi were normal The patient expressed herself as feeling better than she had done for five or six years She had never had any pain in the right kidney which had increased to a length of seven inches and a breadth of three and a half inches It was distinctly moveable, reaching as low as the tip of the iliac crests in the erect posture It was irregular in outline and quite free from tenderness The patient was performing her duties with ease and comfort As the kidney was so moveable she was advised to get an abdominal belt

On Feb 5th the whole of the urine passed in 24 hours was obtained and carefully examined with the following result —

Analysis of Urine

Volume 3100 cubic centimetres; specific gravity 1005, reaction, neutral sediment pus Organic solids 1 12 per cent inorganic solids 0 54 per cent total solids 1 66 per cent water, 98 34 per cent.

Phosphoric anhydride	0 11	

Cammidge s pancreatic reaction was tested upon this urine with a negative result, in both A and B reactions no crystals were found

On Sept 6th, 1904 the patient wrote to say that she had for three days had a good deal of pain in her right side accompanied by hæmaturia She further complained of dimness of sight in the right eye A specimen of urine presented the following characters colour, dark red, obviously from blood, specific gravity 1012, reaction, alkaline, albumin 2 per cent urea, 2 75 per cent, and quantity of urine per diem 80 ounces (2240 cubic centimetres The deposit contained red blood corpuscles in large numbers pus cells in large numbers, epithelial cells (cubical and squamous), and triple phosphates Tube casts were not present With rest the blood and pain disappeared within a day or two but on Sept 18th the hæmaturia again returned in greater quantity, when she consulted Dr Bruce C Kelly of Wells who *kindly furnished us with the following report* on Oct 30th ' There is much blood in the urine The right kidney is nine inches long, four inches broad and three inches thick The quantity of urine passed per day averages 80 ounces or more A fortnight s rest in bed caused the blood to disappear from the urine There is considerable cardiac hypertrophy, *the apex being rather more than* an inch outside the nipple line The aortic second is accentuated and the arterial tension is high There is no albuminuric retinitis but there is swelling and woolliness of both discs in which the vessels are lost

On Nov 21st the patient wrote as follows "I have not had any of my old attacks of sick headache since I saw you in January Recently, however, I occasionally suffer from slight pain at the back of my head, which comes suddenly and as *suddenly disappears* I do not suffer from palpitation now unless I hurry very much In the months of April, May, and June of this year my feet and legs swelled a good deal, but I attributed that to the fact that I was compelled to stand for long hours, they are better now that I can rest more. The pain in my back and side which I had two months ago has disappeared since Dr. Kelly made me rest in bed for a fortnight. I have usually a heavy tired feeling in my back which I can hardly describe as a pain. I am feeling much stronger now, though easily tired on exertion. I am quite able to perform my present duties."

CASE 2.—The patient was a male, aged 43 years. During the last ten years he had been subject to attacks of severe abdominal pain. These attacks came on at any moment, often whilst at work. Each attack laid him up for a fortnight. The pain would commence in the right hypochondriac region and pass round to the back, often being very severe between the shoulders. It did not tend to shoot downwards towards the inguinal regions. The pain was very severe, causing him to break out into a cold sweat. These attacks occurred on an average about twice every year. None of the previous attacks had lasted so long as the present one. None of them had been attended by jaundice, shivering, polyuria, hæmaturia, or vesical irritation. The case was first seen by one of us in an emergency in the temporary absence of his regular medical attendant, Mr. H. W. Freer of Stourbridge, late in December, 1903. The patient was then in great agony, ascribing his pain to the right hypochondriac and right half of the epigastric regions. He was jaundiced and excessively tender in the right upper abdomen. He presented superficially a typical picture of biliary colic, with which diagnosis Mr. Freer agreed on his return. As the condition did not improve he was again seen in consultation with Mr. Freer on Jan. 17th, 1904. The jaundice, though still present, appeared to be slightly less. The pain still continued with occasional acute exacerbations. On palpation a semi-fluctuating mass was felt projecting below the right costal margin and it could be felt extending into the lumbar region. The mass moved with respiration and was very tender to the touch. On percussion it merged with the hepatic dulness and the right kidney could not be felt apart from the mass. His temperature was 101° F., at which point it had kept during the past fortnight. The pulse was 104 per minute and the respirations were 26 per minute. There was no vomiting, diarrhœa, melæna, or loss of flesh. The urine was alkaline, was of specific gravity 1015, but was free from albumin or sugar. A chance word concerning the continuity of the dulness of the tumour with that of the kidney was overheard by the patient's sister (Case 1), who was also present at the bedside. She therefore made mention of her own case, saying that she had suffered from cystic kidneys, one of which had been removed. Three possible diagnoses suggested themselves—viz.: (1) subhepatic abscess arising from the gall-bladder, stomach, duodenum, or appendix; (2) cholecystitis; and (3) enlarged kidney, possibly general cystic disease, suggested by the patient's sister. In these circumstances it was decided to take the patient into the Corbett Hospital for an exploratory operation. He was admitted the same evening (Jan. 17th) and operated upon on Jan. 19th, 1904.

Operation.—An incision was made over the gall-bladder in the right linea semilunaris. The gall-bladder and bile-ducts were found on digital examination to be healthy and quite separate from the swelling. It was then ascertained that the mass which projected below the costal margin was behind the peritoneum and that it was in the position of the right kidney. Before closing the anterior abdominal incision the left kidney was examined and was found to be slightly enlarged but perfectly smooth on the surface. A second oblique incision was made in the right lumbar region and the kidney was exposed and was found to be enlarged enormously and the seat of general cystic disease. As the organ appeared to be functionally useless and the origin of his agonising pain it was deemed advisable to remove it, especially since the left kidney showed no irregularities upon the surface. Nephrectomy was performed without producing any great shock to the patient. The artery, vein, and ureter of the kidney were secured separately by silk ligatures.

Pathological appearances.—The excised kidney on removal weighed 1 pound 9 ounces (708·5 grammes) and had the following measurements: length, five and a half inches (13·75 centimetres); breadth, three and a quarter inches (8·75 centimetres); and thickness, two and a half inches (6·25 centimetres). It was quite soft to the touch and its surface was studded with thin-walled cysts varying in size from that of a pin's head to that of a small Tangerine orange. The cysts were situated in the kidney substance and were not evacuated on removing the capsule. The contents of one of the large cysts was aspirated and examined in order to ascertain if it contained urinous substances. The following is the result of the examination. Microscopically, epithelial cells and cholesterin crystals; chemically, urea 0·18 per cent. and proteid 0·42 per cent. Into one of the branches of the kidney pelvis was injected a solution of methylene blue at considerable pressure. On making a section of the kidney eight hours afterwards it was found that several of the cyst contents corresponding to that division of the pelvis were stained with the methylene blue showing that there was a continuity between the kidney pelvis and the interior of some of the cysts. After making a section of the kidney it was found that the cysts were present in both cortical and medullary portions of the kidney, but that they were more numerous in the medullary portion and that a distinct layer of normal kidney tissue could be recognised by the naked eye on the surface of the kidney, whilst no normal kidney tissue could be seen in the deeper parts. The contents of the cysts varied from clear fluid to dark-brown gelatinous substance. There was no contraction or dilatation of the kidney pelvis or of the ureter and no calculi were found in any portion of the kidney substance or pelvis.

Microscopical sections.—These showed that the cysts were situated in both cortical and medullary portions. The cysts were usually lined by a single layer of epithelium varying from the simple squamous to the high columnar type. Occasionally a cyst was devoid of epithelial lining but there was no evidence of Malpighian bodies attached to any of the walls of these cysts as have been described in other cases. Many of the cysts were surrounded by a fairly dense layer of connective tissue, whilst others had no such fibrous support. The contents of the cysts largely consisted of homogeneous substance, staining a deep yellow with van Gieson's stain. Many cysts, however, contained catarrhal cells, polynuclear leucocytes, and even concentrically laminar bodies, very similar to those found in cysts of the prostate gland. Several of the cysts in this kidney presented beautiful dendritic intracystic projections lined by cubical cells similar to the lining of the cyst. As in Case 1, there appeared to be every gradation in size between the ordinary tubules and the larger cysts. There were large areas of perfectly healthy tissue, there were still larger areas in which the tubules showed the typical appearance of a chronic parenchymatous nephritis, and there were areas of loose fibrous tissue in which the tubules seemed to have disappeared altogether. As in Case 1, there was widespread destruction of Malpighian bodies apparently due to a process of thrombosis with subsequent cicatricial overgrowth. The connective tissue of the kidney was generally increased and there were large tracts of round-celled infiltration indicative of inflammatory reaction. The degree of cystic change in Specimen 1 was much more advanced than in Specimen 2, and despite the absence of macroscopic evidence of healthy kidney tissue there were large tracts of normal kidney tubules in each specimen that appeared to be capable of performing excretory functions with a varying degree of efficiency.

After-history.—The patient rallied from his operation very satisfactorily. His temperature remained normal for three days, after which it began to fluctuate, rising in the evening to 101°, 102°, and 103°, and falling in the morning to 98°. This fever was due probably to phlebitis which began in the right femoral vein and later spread to the left femoral vein. The lumbar wound remained healthy for about a week after operation when it was opened up in the hope of finding retained suppuration to account for the fluctuating temperature. No pus was found but the wound now became infected and continued to discharge up to the time of death. This long-continued discharge was doubtless due to infected silk ligatures. The wound in the linea semilunaris healed by primary union. A faint haze of albumin was discovered in the urine for the first time on Jan. 24th, five days after operation. Pus was discovered in the urine for the first time on March 4th, six weeks after the operation. This was accompanied by tenderness over the left kidney; tube casts were noticed in the urine shortly after this, which facts strongly suggest that the left kidney became the seat of pyelonephritis about this date. The left kidney was carefully watched during his stay in hospital and it was felt gradually to increase in size, becoming palpable about three weeks after the operation and later becoming irregular on the surface, suggestive of general cystic disease. Although the amount of urine was increased, for a time its specific gravity was maintained. Towards the end of his sojourn in hospital, however, the renal secretion diminished in quantity and deteriorated in quality, as shown by the specific gravity. The reaction of the urine varied considerably; though generally alkaline there were days, and even weeks, when it was acid. On April 12th, 1904, a careful microscopical and analytical examination was made with the following result:—

Analysis of Urine.

Volume, 1215 cubic centimetres per diem; specific gravity 1012; reaction, alkaline; sediment, triple phosphates, tube casts, and an enormous amount of mucus. Organic solids, 2 03 per cent.; ash, 0 93 per cent.; total solids, 2 96 per cent.

	Per cent.		Per cent.
Urea...	1·25	Ethereal sulphates (SO_3)	0 013

Chlorine...	0·425	Water	97·04
Inorganic sulphates (SO_3)	0·139		100·00

Cammidge's pancreatic reaction was tested upon this urine with a negative result. In both the A and B reactions no crystals were deposited. Whilst the patient remained in hospital there was no cardiac hypertrophy but there was some accentuation of the aortic second sound. There were little or no arterial sclerosis and no increased vascular tension. He had slight swelling of the feet, due partly to the femoral phlebitis. There was never any œdema of the lungs and his ocular fundi were perfectly normal. He left hospital on May 18th with a small discharging sinus, able to walk and to get about. After leaving hospital his strength did not return, owing to which he was compelled to spend a large part of the day lying down.

Seen by one of us in the middle of June in consultation with Mr. E. Fryer of Cradley the patient was then very anæmic and complained of great pain in the left kidney and of difficulty in getting about owing to weakness and breathlessness. His feet and legs showed œdema and there was œdema at the bases of both lungs. There was no ascites. The left kidney was much enlarged, irregular in outline, and tender on palpation. In length the kidney measured seven inches and in breadth three and a half inches; its lower end reached to the anterior superior iliac spine and anteriorly as far as the linea semilunaris. There was now some cardiac dilatation but the blood pressure was not, to all appearances, increased. The urine contained a large quantity of albumin and pus. Mr. Freer, who attended him just previously to his death, gives the following account of him. "The left kidney was as large as the right one previous to its removal. The patient became more and more emaciated and anæmic. The heart was dilated, the apex beat being felt outside the nipple line. The pulse gradually became quick, feeble, and irregular. There was considerable œdema in the lower extremities and a mild degree of ascites. The upper extremities and face were free from œdema. The sinus in his right side failed to heal up. Up to the very end the patient suffered severe pain in the region of the left kidney. A week before his death the urine became scanty and almost suppressed and contained a considerable amount of albumin. Death occurred in August, 1904, seven months after his operation."

Summary.

[illegible]

1904. January: Three slight attacks of migraine. September: Right [illegible]

[illegible]

1903. [illegible] jaundice; [illegible]

1904. Ja[illegible] infection [illegible] Rapid enla[illegible] June: Failure of general health, increasing cardiac weakness. August: Increasing cardiac and renal inefficiency; partial suppression of urine; death.

Remarks.—The occurrence of this rare disease in two members of the same family is a point of unusual interest. The patient in Case 1 suspects that another brother of hers is also affected with general cystic disease of the kidneys because he suffers from severe headache, pain in the loin, and occasional attacks of frequency of micturition. A specimen of the urine of this third member is, however, perfectly healthy, but as he refuses to submit himself to medical examination there has been no opportunity of ascertaining if the sister's suspicion is correct or not. Carl Beck[1] records a case of multiple cysts in the kidney upon which he performed nephrectomy and in this instance no less than three sisters suffered and died from the effects of this disease. This family tendency is not mentioned amongst the collected cases of Ritchie[2] and others, yet it is quite certain that such occurrences are not accidental and that they point to a constitutional tendency which is, at least, a predisposing factor in the etiology of the disease. The age at which this disease was noticed in the foregoing cases is almost identical with the average of general cystic disease of the kidney in the adult—viz., 45 years. The history in each case points to renal mischief extending over nine or ten years, so that the onset of the disease was very slow. There is probably a period of years of gradual development in which symptoms exist more or less severely, but during which a physical examination is either never made and thus a possible enlargement is undiscovered, or, if such an examination is made, the enlargement is not sufficiently marked to call for special attention. Several cases, however, in our own experience have never consulted a medical man until one or both of the kidneys had assumed enormous dimensions, showing that the disease is occasionally symptomless for some considerable time.

The two cases under discussion present some clinical features worthy of notice. It is impossible to say whether the calculi passed by Case 1 in 1893 had any causal relationship to the onset of the disease or were secondary to its establishment. For five years the same case was subject to severe headaches which were entirely relieved, for three years at least, by nephrectomy. These headaches can scarcely be similar in nature to those which occur in Bright's disease, otherwise the removal of one kidney would not have cured them seeing that the opposite kidney was also affected. It is more than likely that this migraine was due to mobility of the left kidney and that the removal of this organ cured them as nephropexy or nephrectomy does in cases of ordinary moveable kidney who have previously suffered from severe headaches. Two and a half years after the operation there was a slight recurrence of migraine, due, no doubt, to mobility and dragging of the enlarged right kidney. The attacks of severe lumbar pain which so frequently attend the development of this rare disease have been explained in various ways, as, for example, by mobility of the kidney, sudden tension of the cyst contents, hæmorrhage into cysts, or the passage of blood, mucus, crystals, or calculi down the ureter. We are convinced, however, that sudden lumbar pain is occasionally due to rupture of cysts and the extravasation of their contents into the loose tissue around the kidney. This is borne out by the cicatrices seen on the surface of some of the specimens of cystic kidney. The thin wafer-like walls in some of the cysts in Specimen 1 clearly indicate how easily such a rupture could be produced. The jaundice of Case 2 was probably due to the rupture of a cyst at the inner and upper pole of the right kidney, the extravasated contents of which pressed upon the common bile-duct and so produced obstructive jaundice. In another case of general cystic disease well known to one of us the following development occurred. The patient was suddenly seized with an attack of acute lumbar pain. On examination a fluid swelling was found in the lumbar region which ran forward into the muscles of the abdominal wall. The swelling was regarded by an eminent surgeon as a possible dissecting aortic aneurysm. Subsequently this swelling disappeared of itself and six months afterwards at the patient's death it was found that he had been suffering from general cystic disease of both kidneys. There was little doubt in this case that a superficial cyst had ruptured, accounting for the sudden attack of lumbar pain and the production of the fluctuating swelling.

The diagnosis of this disease may be in advanced cases a matter of comparative ease, or, as in the case just referred to, even to the last it may remain very obscure. Although this case had been seen by many specialists both in London and Birmingham cystic kidney was never diagnosed, chiefly because the huge kidneys were well anchored under the costal margin, so that they could not easily be palpated. When the organ falls below the costal margin there is a much better chance of palpating its surface and of discovering the highly characteristic irregularities and possibly fluctuating areas. Bilateral enlargement is very suggestive of general cystic disease. In Case 1 sufficient importance was not attached to the slight enlargement of the right kidney, as the physical characters of the left renal enlargement were absolutely typical of general cystic disease. The pathological characters of the urine are not sufficiently striking to help us much in the diagnosis of the disease. The urine is generally increased in quantity, often considerably so, but deficient in quality, showing a low specific gravity and a deficiency of solids. The reaction is generally alkaline but for short periods it may be acid. There are generally pus, red blood cells, and epithelial cells present in varying quantities. The urine contains albumin or globulin which, however, is generally derived from the pus, blood cells, or epithelial cells, since the filtered urine is proteid-free. Peptone and reducing substances like sugar are absent. Nitrogenous metabolism, as indicated by the excretion of urea, uric acid, hippuric acid, and creatinine, is for the most part sluggish. Intestinal putrefaction, as shown by the small percentage of ethereal sulphates and the absence of phenol, is low. Phosphates and chlorides vary considerably in amount according to the special diet taken. Hippuric acid is sometimes absent, in other cases it appears in the urine in larger quantities than normal. Tube casts are not as a rule present in this disease; they were met with in Case 2 which, however, was complicated with a nephritis. We have never seen any of those granulated cylinders in the urine which are described by certain observers. It is evident, therefore, that the renal secretion in general cystic disease is almost identical with that found in hydronephrosis and in some cases of pyonephrosis of calculous origin. One is therefore compelled in making a differential diagnosis to rely upon physical examination and especially to look out for such characters as irregularity of outline, a general solid firmness with fluctuating areas and a bilateral tendency which occurs in this disease. The method adopted by Hoehne of puncturing the cysts in order to discover whether the rosette bodies described by him are present or not is a procedure of very doubtful value and is fraught with some danger. These rosette bodies, which correspond to the concentrically laminar bodies described by us, are not present in every cyst. It is difficult to puncture cysts at such a depth, for, obviously, it can only be done safely through the loin. Cysts may become very superficial when the kidney passes out anteriorly below the costal margin but if an attempt is made to puncture them in this situation there is a great danger of fouling the peritoneal cavity either by accidentally puncturing the colon or by infecting it with contents of the cysts which are not always sterile. A much safer and more scientific procedure in all such cases, whether the diagnosis of cystic disease is certain or not, is to expose the mass by the usual lumbar incision. In this way alone can the surgeon in many cases make an absolute diagnosis and, at the same time be in a position to treat the case as he finds it.

[1] Annals of Surgery, vol. xxxiii., p. 147.

[2] Laboratory Reports, Royal College of Physicians of Edinburgh, 1892.

In perusing the literature of this obscure disease one realises how scanty is the material which can be of service in determining which is the best line of treatment to adopt. The dread of post-operative suppression and uræmia in this disease seems to have acted as a paralysing agent on the minds of physicians and surgeons. It is natural, perhaps, to imagine that a large cystic kidney like that of Case 1 is functionally useless and that the opposite one is doing all the work. If this were the case the remaining kidney would not rapidly increase in size after operation as it did in each of the cases just described. Furthermore, when careful microscopical examinations are made of these large cystic kidneys large areas of perfectly healthy, and still larger areas of partially healthy, kidney tissue are found, which, however, are not visible to the naked eye. It is quite certain that the ever-increasing pressure of growing cysts must slowly strangle and render functionless the areas of secreting tissue around them, but it is impossible by superficial inspection to estimate when that destruction has become complete. For this reason it is questionable whether the operation of nephrectomy is ever justifiable in general cystic disease. Several surgeons imagine that if one kidney is cystic and the other is apparently normal to the touch it is good treatment to remove the cystic organ on the supposition that it will prevent cystic development in the other. In the first place, one cannot detect early cystic changes by simple palpation of the kidney through an exploratory wound into the peritoneal cavity; and, in the second place, cystic disease is not infectious in the same sense as tuberculosis of the kidney is. It is more than likely, even if one kidney is healthy, that the increased demand made upon it when its less fortunate partner is removed must augment its tendency to cystic disease. One realises, of course, that severe symptoms such as were present in both of these cases must call for serious attention on the part of the surgeon. The operation of nephrectomy was justified in Case 1, in so far as it has given the patient three years of comfortable and useful life, though it will in all probability shorten her existence. Nephrectomy is too extreme a remedy to adopt in a disease which is probably constitutional and not local in nature. It always means the removal of excretory tissue the functional capacity of which one can never accurately estimate and the throwing of the entire work of urinary secretion upon the opposite kidney, which is, in all probability, in an earlier stage of the same disease.

The operative measure which has so far given the best results is that of free incision of the diseased kidney. A case so treated by Curtis[3] was alive and well ten years after operation; another by Kammerer[4] was alive and well three years after operation; in both these cases the affection was bilateral at the time of operation. This mode of procedure consists in the free incision of the cortical substance and the systematic opening of all the larger cysts which are then packed with gauze in order to secure their entire obliteration. In this way the size of the organ and the pressure within its capsule are enormously diminished. The compression of the more or less healthy tubules is thus relieved. The kidney is thoroughly anchored in the loin and the symptoms dependent upon mobility disappear. This free incision does not appear to be attended by the formation of permanent fistulæ unless there is some contraction of the kidney pelvis, in which case the establishment of a fistula would be an advantage to the sufferer. There is also very little risk of severe hæmorrhage. Such a method of operative procedure, when applied first to one kidney and then to the other as they increase in size, must best preserve for a longer or shorter time the functional capacity of the diseased organs and thereby prolong the life of their unfortunate possessor. Suppression and uræmia are less likely to follow the operation of free incision than when complete nephrectomy is performed, simply because the increased nitrogenous elimination occasioned by operation is shared by both organs. Among the indications for operation in cystic disease of the kidney the following may be mentioned—attacks of severe lumbar pain, vomiting, hystero-epilepsy, migraine, and threatened suppression or uræmia.

We purposely avoid discussing the pathological significance of these specimens at the present time as one of us intends to publish shortly a paper bearing specifically upon this subject.

The after-history of these two cases is somewhat different. Case 1 is still in fairly good health and able to perform the duties of housekeeping with comfort. We gave her, in our own minds, about one year of life after her nephrectomy; she has obviously outstripped that expectation by several years. It only shows how functionally active these large cystic kidneys are and how slow we should be to condemn such diseased organs as useless. In Case 2 the chances of the patient's recovery became hopelessly handicapped when sepsis and pyelonephritis set in. He never really regained anything like his normal health and he eventually succumbed to a combination of renal and cardiac inefficiency. It is thus obvious that although nephrectomy was performed in each of the cases just related with a varying degree of success we would after careful consideration advise in future cases free incision rather than removal of the kidney.

In conclusion, we wish to thank Mr. Barling for permission to publish his case and Dr. Tibbetts, Dr. Kelly, and Mr. Freer for their willingness and courtesy in supplying us with some of the facts concerning the cases.

SOCIETY OF APOTHECARIES OF LONDON: UNVEILING OF ST. LUKE'S WINDOW.—Owing to the visit of the King of Spain to the City on June 7th next the unveiling will take place on Monday, June 5th, instead of June 7th, as originally arranged.

TWO CASES OF GANGRENE WITH SPONTANEOUS AMPUTATION.

By E. OWEN THURSTON, M.B., B.S. LOND., F.R.C.S. ENG.,
CAPTAIN, I.M.S.; RESIDENT SURGEON, MEDICAL COLLEGE HOSPITAL, CALCUTTA.

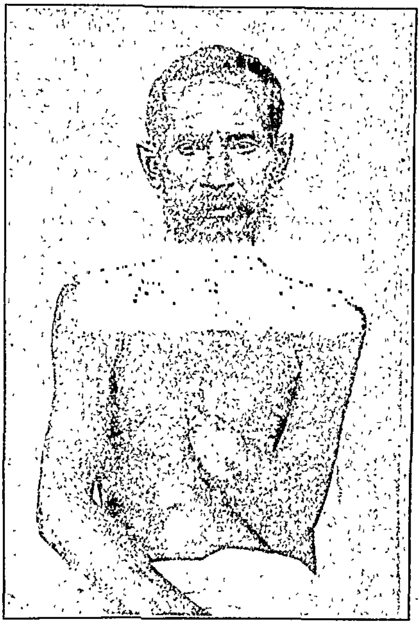
THESE two cases show to what an advanced stage natives of India will allow disease to progress before applying to a hospital for relief. The first case was under the care of Major D. M. Moir, I.M.S., to whom I am indebted for permission to publish it; the second was under my own charge when officiating as professor of surgery at the Medical College Hospital.

CASE 1.—The patient, a Hindu male, aged 50 years, was admitted to hospital on Sept. 12th, 1904. In January of the same year he noticed that the tips of the fingers of the left hand had become insensitive; the anæsthesia spread upwards to about the middle of the forearm. A week later he suffered from fever and 15 days from the commencement of the anæsthesia a small bleb was noticed in the cleft between the thumb and forefinger which broke down and ulcerated, more blebs appeared, and the soft tissues of the hand and forearm gradually sloughed away until by April (four months) only the bones of the hand and wrist were left. During this time he suffered a good deal of pain and there was continuous fever, a large quantity of pus was discharged, and he became weak and emaciated. In the same month he had a fainting attack and a local practitioner was called in who administered stimulants and soon afterwards amputated at the wrist. Towards the end of April a line of demarcation formed in the upper part of the forearm; the soft tissues and finally the bones dropped off while he was applying a lotion made from "*nim*" leaves. The fever which had been continuous up to that date ceased after the separation of the gangrenous part.

On admission the following history was obtained. He had suffered from syphilis 30 years ago but had never had rheumatism or any heart trouble, nor was there any history of injury. On examination of the heart reduplication of the second sound was detected down the right side of the sternum, otherwise the physical signs were normal. The peripheral arteries were not markedly atheromatous. The urine contained no albumin. The left forearm had spontaneously separated about the middle with the formation of a conical ulcerated stump. Major Moir amputated through the condyles of the humerus with a posterior elliptical skin-flap on Sept. 21st; the arteries were found to be thrombosed. A portion of the end of the flap sloughed and the bone protruded, but in spite of this the wound shortly healed. Convalescence was retarded by an attack of pneumonia in the beginning of October. He left hospital completely cured on *Dec. 5th.*

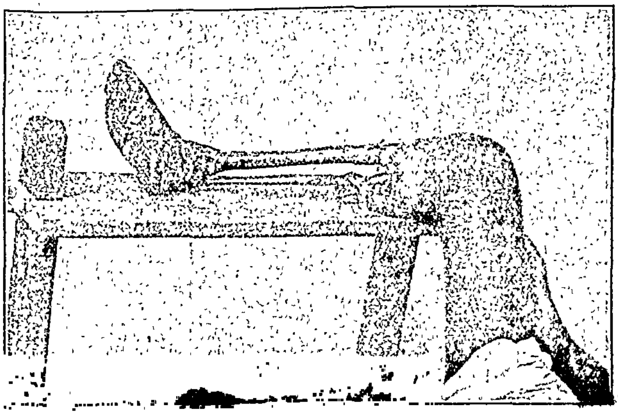
CASE 2.—The patient was a Hindu male, aged 40 years, and was admitted into the Medical College Hospital on May 7th, 1904, with gangrene of the right foot and leg. Four months before admission he suffered from fever, probably malarial in origin. On the tenth day of this attack he suddenly felt a burning sensation in the right leg accompanied by severe pain which was shooting in character and referred mainly to the distribution of the sciatic nerve. Within 24 hours the limb became insensitive and cold and then gradually began to swell and to assume a reddish appearance. The pain increased for some days and then gradually diminished. The fever ceased about ten days from the commencement of the leg trouble. One month later he noticed that some small blisters appeared over the leg and foot; these persisted for about three weeks, accompanied by the discharge of thin serous fluid; the leg at that time became more painful and there was much itching in the limb. About one month before admission sloughs appeared, at first just above the heel but later extending up the leg, and the foot became mummified. The sloughs gradually separated, the patient himself removing them when loose, until finally only the bones remained from the ankle to the level of the tubercle of the tibia.

FIG. 1.



On admission no *history of syphilis or other previous* illness was obtained; the patient appeared to be fairly

FIG. 2.



healthy. The heart sounds were weak, giving one the impression that the muscle was flabby; no murmur could be detected. No atheromatous changes were found in the peripheral arteries. The urine was of low specific gravity but contained no albumin or other abnormal constituents. The right foot was mummified and black; above it with the exception of the ligaments of the ankle-joint only the bare bones of the leg remained up to just below the level of the tubercle of the tibia and here the bones had been deeply eaten into by the granulations of the stump. On the day following admission the fibula and, shortly after, the tibia separated. The thigh was amputated by a modified Stokes-Gritti's method on May 13th, the posterior flap being made longer than usual on account of there being more skin available on this aspect of the leg. The patella was small; its cartilage was only partially removed and it was fixed in position by silk sutures passing through the periosteum of the femur. There was a little suppuration and the patient was discharged with a small sinus on July 9th, the patella being firmly adherent to the femur and the stump satisfactory.

Captain Leonard Rogers, I.M.S., examined the specimen and reported that "the lumen of the artery was nearly blocked by partly organised blood-clot with a small canal through it. Microscopically the inner elastic lamina was clearly seen and no atheromatous changes found."

These two cases in conjunction seem to be worth reporting as they show an advanced stage of gangrene which is rarely seen at the present day. The first case from the slower onset was probably due to thrombosis, the second to embolism from a thrombus forming in a weak heart during an attack of fever. Unfortunately, in the first case the arteries were not examined.

Calcutta.

EPIDEMIC CEREBRO-SPINAL MENINGITIS AND POSTERIOR BASIC MENINGITIS.

By O. HILDESHEIM, M.D. Oxon.,
LATE HOUSE PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

There is a widespread belief—more particularly outside England—that posterior basic meningitis is a sporadic form of the epidemic disease. Koplik, for example, in his recent work on the Diseases of Children deals with the epidemic disease briefly and dismisses posterior basic meningitis with the remark that it is considered a separate disease in England and that it runs a protracted course.

Posterior basic meningitis accounts for one-third of all the cases of meningitis amongst the in-patients at Great Ormond-street Hospital (133 out of 396 consecutive cases). By the kindness of the staff of that hospital I have recently had the opportunity to investigate the histories of over 100 cases of posterior basic meningitis and the present seems an opportune time to record briefly and as far as our present knowledge permits in what points this disorder stands out and apart from epidemic cerebro-spinal meningitis as a disease *sui generis*.

No doubt the ultimate decision rests with the bacteriologists, but the bacteriology of the cerebro-spinal fluid is just now at a very perplexing stage. For example, Hunter and Nuthall in nine cases of posterior basic meningitis found a diplococcus identical with the meningococcus. In three cases the culture was pure, in three it was associated with the influenza bacillus, in one with the tubercle bacillus, and in one with staphylococci. Mya described three cases of fibrino-purulent meningitis in breast-fed infants in which the Pfeiffer bacillus was present. Gleon obtained these bacilli from the fluid yielded by lumbar puncture in a child eight months old. Schultze mentions a number of instances in which the pneumococcus has been found "in the so-called sporadic cerebro-spinal meningitis," and adds that it is found not seldom ("*nicht selten*") in the epidemic form. Osler says: "The pneumococcus has been found frequently in association with the diplococcus of Weichselbaum in cerebro-spinal fever." The pneumococcus, indeed, appears to be almost ubiquitous. "No organism is more variable than the pneumococcus in its virulence and pathogenic results. ...... The form of primary meningitis set up by the pneumococcus may in every detail apparently resemble the post-basal form described by Lees and Barlow, or the epidemic cerebro-spinal form." (Leith.)

It is very important to realise that one has not necessarily found the cause of the disease because one has shown the presence of a potentially pathogenic organism in a case of meningitis. I had under my observation a case which the physician in charge considered an example of pneumococcus meningitis. I performed a lumbar puncture and the pathologist reported that he obtained a pure culture of pneumococcus. Nevertheless, the necropsy revealed a typical tuberculous meningitis.

Clinically the epidemic disease shares many features in common with posterior basic meningitis. To those who consider the two diseases identical the differences are comparable to those which are found when two separate epidemics are contrasted. As Osler says, "The clinical features of the sporadic form present interesting variations which are worthy of additional study."

1. Although it proves nothing, it is a very interesting fact that our knowledge of the sporadic disease antedates the earliest descriptions of the epidemic fever by several years. Nothing was known of the epidemic disease before the nineteenth century and there was no description of its occurrence in the British Isles before 1830. Nevertheless, that one type of posterior basic meningitis was common enough in 1827 is shown by the description which Alexander Monro (the third generation of that family of great physicians) gave in his work on the Morbid Anatomy of the Brain, published in that year. Dealing with chronic hydrocephalus he remarks that the 14 cases which he himself had seen were *all born with* large heads and continues: "But according to some authors the disease appears soon after birth or even a few years after it. The child seems dull. This dulness is accompanied with headache and fever, which is much more severe at times and is attended by sickness and vomiting. The appetite is impaired and the food is apt to excite nausea. The headache becomes more severe and constant and is *accompanied by pain and stiffness in the neck* and with frequent and irregular pulse, but in some cases is slower than natural. The eye is dull and the vision is indistinct; the skin is hot and the pulse frequent and irregular. The urine is discharged with pain and difficulty. After the above symptoms the head expands." No one familiar with the disease would deny that this is a very succinct account of one form of posterior basic meningitis which results in hydrocephalus.

2. There is a very definite difference in the age incidence of the sporadic and epidemic diseases. Osler says that more than half the cases of the latter are in persons under ten years of age. More than half the cases of posterior basic meningitis are in infants under one year of age.

3. The protracted nature of many of the cases of posterior basic meningitis has no parallel in the epidemic disease. The significance of this difference which is generally recognised is difficult to gauge. Most of the sequelæ of the former disease are associated with internal hydrocephalus. For this reason and on account of its altogether insidious nature it is very difficult to give any general pronouncement on the duration of the disease. But there is every reason to suppose that the inflammation of the meninges not infrequently endures for several months.

4. I find nothing in the accounts of the epidemic illness of amaurosis without optic neuritis which is so remarkable a feature of posterior basic meningitis and which occurs in one-third of all the cases of that disease (27 out of 78 of my cases).

5. On the other hand, optic neuritis seems fairly common in epidemics (six out of 40 cases—Randolph). It is very rarely met with in posterior basic meningitis. There was only one undoubted instance in the whole of my series of cases.

6. "Moos found in 64 cases of recovery from cerebro-spinal fever that 55 per cent. of the persons were deaf." Only three of my cases complained of subsequent deafness. In one of these it was very slight and associated with large tonsils and adenoids and in another it was after three operations for subdural drainage. So that in only one case did it follow directly from the primary disease and it must be concluded that deafness is a rare sequel of posterior basic meningitis.

7. Skin lesions, although they occur, are much less common in posterior basic meningitis than in the epidemic fever. In my series herpes, which is so characteristic of cerebro-spinal fever, is only described twice. I know nothing of petechial rash in the sporadic disease. Osler, in his

description of cerebro-spinal fever in the Encyclopædia Medica, says: "A petechial rash, which was so common in the early epidemics that the disease had the name of spotted fever, was present in more than one-third of our cases."

8. There are further minor yet significant symptoms in posterior basic meningitis, such as retraction of the upper eyelids, which I do not find mentioned in the accounts of epidemics. How far these differences are dependent upon the earlier age incidence of posterior basic meningitis it is impossible to say. It is noteworthy that in that disease amaurosis is less common in older children.

A SECOND CASE OF PNEUMOCOCCUS ENDOCARDITIS TREATED BY ANTI-PNEUMOCOCCUS SERUM.

By T. J. HORDER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, GREAT NORTHERN CENTRAL HOSPITAL;
AND
H. C. L. SCOFIELD, M.B., C.M. EDIN.,
EXAMINER AND LECTURER TO THE ST. JOHN AMBULANCE ASSOCIATION.

IN THE LANCET of June 4th, 1904 (p. 1561), one of us (T. J. H.), with Dr. A. E. Garrod, reported a case of pneumococcus endocarditis treated by anti-pneumococcus serum. *The disease was very acute and the whole duration* of it probably not longer than three weeks. The pneumococcus was cultivated from the blood three days after the patient was first seen. A case has recently come under our observation which was of longer duration, lasting more than two months. But a bilateral pneumonia, followed by a double empyema, occurring in a child convalescing from rheumatic fever constituted a very serious condition from the first. And the presence of pneumococci in the circulation was not demonstrated until quite late in the course of the illness. Nevertheless, seeing that during the present state of probation of bactericidal sera accurate diagnosis in the cases treated by them is of the utmost importance, it is considered advisable to publish a brief account of the case.

The patient, a boy, aged ten years, suffered from enlarged tonsils and slight sore throat at the beginning of November, 1904. On Nov. 18th he was taken suddenly ill with headache, pains in the back and limbs, and a rise of temperature (101° F.). On the third day the joints were painful and swollen. He was seen by one of us (H. C. L. S.) and the disease was diagnosed as acute rheumatism. On the fourth day a mitral systolic murmur was heard. Sodium salicylate was given; the pains in the joints passed off and the temperature fell to normal on the eleventh day. On the thirteenth day the temperature rose to 102° and signs of [illegible] ng appeared. On [illegible] the left side; the [illegible] nd oxygen inhalations became necessary. Defervescence took place by lysis, the temperature becoming normal again on the twenty-first day; but thenceforth it rose daily to from 100° to 101° until the twenty-seventh day. The signs in the lungs remaining, the right pleura was explored; pus was discovered; a portion of a rib was resected and an empyema was drained by Mr. T. Crisp English. The intermittent fever continued. On the thirty first day the left pleura was explored with a similar result, a second empyema being opened and drained. The intermittent fever still persisted (102°–103°) despite efficient drainage of both empyemata. The mitral murmur was still heard and the pulse averaged 140. On the fifty-first day the patient was [illegible] C. B. Lockwood who found no [illegible] us of suppuration but suggested [illegible] The *patient was also seen in consultation* by one of us (T. J. H.) on the same day and a blood examination was made. A blood count showed a leucocytosis of 11,600 and a blood culture grew pneumococci in considerable numbers in each of six culture tubes. By this time loss of flesh had become very marked, the patient being quite emaciated. Anæmia was also marked. The heart murmurs pointed to the presence of mitral obstruction and incompetence. Both empyema wounds were discharging freely; the pus contained pneumococcus together with staphylococcus albus and bacillus coli communis. The urine was natural. On the fifty second, fifty-third, and fifty-fourth days respectively ten cubic centimetres of Pane's serum No. 2 were injected subcutaneously. This was repeated on the fifty-eighth and sixtieth days. On the sixty-second day signs of nephritis appeared: œdema, albuminuria with blood and epithelial casts, and severe headache. On the sixty-fourth day the urine became very scanty; on the sixty-fifth day the temperature became subnormal and the patient died comatose on the sixty-sixth day.

No good result seemed to follow either of the two periods of administration of the serum. The patient was so much exhausted by his disease at the time the serum was used that its failure seemed inevitable The fact that the leucocyte count amounted to 11,600 only in a pneumococcal infection in a patient aged ten years showed that the resistance was much lowered. If, as recent researches seem to prove, we are dependent upon the patient's tissues for their reaction to the stimulus provided by a bactericidal serum, that is, the *action is not a direct but an indirect one, it is easily* understood why failure should follow the serum treatment in this case. The importance of early diagnosis of the existence of septicæmia, and the nature of it, becomes obvious. Death with the symptoms of a terminal nephritis is a common event in malignant endocarditis, and the occurrence of these symptoms is always a matter of the utmost gravity in such cases.

CONGENITAL ELEVATION OF THE SCAPULA.[1]

By CHARLES R. KEYSER, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CANCER HOSPITAL, LONDON; LATE CLINICAL ASSISTANT TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

JUDGING from the number of recorded cases this deformity is rare and as I have recently had the opportunity of observing one I have put together a few facts concerning this malformation in the hope that they may be of interest to the members of this society. The patient was shown at a meeting of the society on Jan. 22nd, 1904.

The patient, a girl, aged nine years, was taken to the Victoria Hospital for Children on Dec. 17th, 1903, because of deformity of the left shoulder-blade, which had been noticed for one month. There was no history of accident or infantile paralysis No other member of the family had a similar or any other deformity. The patient had always been "delicate" but had had no definite symptoms. On examination the left scapula was found to be two and a half inches higher than the right but the bone was of the same size as its fellow. Movement of the arm, both active and passive, was normal. There was no osseous bridge to be felt between the vertebral border of the scapula and the spine, nor was there any lateral curvature of the spine. The spinous process of the third dorsal vertebra, however, felt thicker than normal and was apparently displaced slightly to the left. The inferior angle of the scapula *was on a level with the interval between* the sixth and seventh dorsal spines. There was no paralysis of any muscle. The x rays showed nothing abnormal and the two arms were of the same length. The child's head was rickety in appearance but there were no other signs of rickets or of any other deformity. The teeth were slightly notched and ridged, as is generally the case in ill-nourished children. As the child suffered absolutely no pain or inconvenience from her condition no active treatment was adopted, especially as the deformity was barely visible, except when the patient was undressed. In the only other similar case with which I am acquainted, where operative measures were adopted in order to correct the deformity, very little, if any, benefit followed a very severe operation.

Cases of congenital elevation of the scapula may be classified into four groups: (1) where there is a bridge of bone between the vertebral border of the scapula and the spine; (2) where there is absolute absence of one or more muscles forming the shoulder girdle; (3) where there is a long and everted supraspinous portion of the scapula; and (4) where there is no osseous bridge and the scapula is normal or smaller than usual, with short or otherwise defective muscles. The great majority of recorded cases fall under the last group. Cases falling under the second group are very rare, only five instances having been met with. The most interesting cases are those where there is an osseous bridge between the scapula and the spine, as it is still undecided how this piece of bone is formed. Moreover, it can be dealt with surgically with most gratifying results. When present it is usually triangular in shape, the base being attached to the vertebral border of the scapula and the apex to the spinous process of either the seventh cervical or the first dorsal vertebra. In many instances the actual union to the scapula and spine is by cartilage which allows a certain amount of movement. The arm, however, can rarely be raised beyond a right angle. Various theories have been brought forward to explain the presence of this abnormal bridge of bone, the chief of which are that it is formed in connexion with the vertebræ and afterwards becomes attached to the scapula, or that the reverse of this is the case, or that it is independent of both.

---

[1] A paper read before the Clinical Society of London on Nov. 11th, 1904.

Mr. A. Willett and the late Mr. W. J. Walsham described the first two cases, records of which are to be found in the Transactions of the Royal Medical and Chirurgical Society for 1880 and 1883 respectively. In the first of these there were multiple deformities present besides that of the scapula. The clavicles, the ribs, and the sternum were all abnormal and in addition there were 12½ vertebræ missing. The left scapula, which was fixed by a broad ridge of bone to the spine, was much shorter than normal and was in appearance more like a scapula at birth. The osseous bridge was partially united by cartilage to the scapula. The second case was that of a girl, aged eight years, whose left scapula was one inch higher than the right. A triangular bridge of bone between the scapula and the seventh cervical vertebra was present which caused much impairment of movement of the arm. The osseous bridge was removed and was found to be connected to both the spine and scapula by a layer of cartilage. Similar cases have been recorded by Mr. Goldthwaite and Mr. Painter,[2] by Mr. H. S. Collier,[3] and by Mr. Hibbs and Mr. Loewenstein.[4] Maydl[5] has related two similar cases; in both the left scapula was affected and a bridge of bone was present, and both the patients were girls. Removal of the osseous bridge restored the normal movements of the arm in both instances. In The Lancet[6] there is a report of a case which Mr. H. J. Stiles showed at the Edinburgh Medico-Chirurgical Society. The left shoulder was affected and a mass of bone was found growing from the upper border of the scapula and was wedged against the transverse processes of the vertebræ. Abduction of the arm was impossible until the osseous bridge was divided.

In discussing the formation of this osseous bridge Mr. Willett and Mr. Walsham regarded it as an "abnormal development of the suprascapular epiphysis, which normally exists as a narrow ridge of bone along the posterior border of the scapula, and consequently as homologous to the suprascapular bone of some of the lower vertebrates. The suprascapular epiphysis in man may actually present an abnormal backward development comparable to that, say, of the rabbit. It is advancing, therefore, but one step further to compare the bridge of bone in our specimens to the distinct suprascapula of the frog, and but one step further still to conceive it united to the spine, as in the skate. This means that the shoulder girdle in these cases has reverted to that of a lower type."

Cases similar to mine, where no osseous bridge is present, have been recorded by Mr. H. B. Robinson,[7] by Mr. Goldthwaite and Mr. Painter and by Mr. Hibbs and Mr. Loewenstein. Mr. H. A. T. Fairbank also showed two cases of this deformity at a meeting of the Clinical Society of London on Oct. 28th, 1904.[8] It has been noticed that the deformity is unilateral and is more often present on the left side than on the right. The neck muscles are usually shortened and other congenital malformations, such as spina bifida, shortness of the arm on the affected side, &c., are frequently present. The deformity has been said by some to be caused by intra-uterine rickets, accident at birth, or an intra-uterine anterior poliomyelitis. The theory, however, which seems to account for the elevation of the shoulder in the most satisfactory manner is that suggested by Sprengel in 1891. He came to the conclusion that the arm became fixed in utero behind the back and thereby caused elevation of the scapula.

IS MAN POLTOPHAGIC OR PSOMOPHAGIC?

By HUBERT HIGGINS, M.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.,

LATE DEMONSTRATOR OF ANATOMY TO THE UNIVERSITY OF CAMBRIDGE AND ASSISTANT SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

During the last four years an entirely new light has been thrown on the problems of human nutrition by the initiative of Mr. Horace Fletcher and Mr. E. H. van Someren. The following is quoted from a report by Sir Michael Foster, made after their visit to Cambridge in the autumn of 1901: "The adoption of the habit of thorough insalivation of food was found in a consensus of opinion to have an immediate and very striking effect upon appetite, making this more discriminating and leading to the choice of a more simple dietary, and in particular, reducing the craving for flesh food. The appetite, too, is beyond all question *fully* satisfied with a dietary which had a total considerably less in amount than with ordinary habits is demanded." Mr. Fletcher's persistence and generosity were responsible for the remarkable work carried out by Professor Chittenden at Yale University. Its importance can be judged from the following extract: "Confining our conclusions to general statements, it may be said that our results, obtained with a great diversity of subjects, justify the conviction that the minimal proteid requirements of the healthy man under ordinary conditions of life are far below the generally accepted dietary standards, and far below the amounts called for by the acquired taste of the generality of mankind. Expressed in different language the amount of proteid or albuminous food needed daily for actual physiological requirements of the body is not more than one-half that ordinarily consumed by the average man. Body-weight (when once adjusted to the new level), health, strength, mental and physical vigour, and endurance can be maintained with at least one-half of the proteid food ordinarily consumed; a kind of physical economy, which, if once entered into intelligently, entails no hardship but brings with it an actual betterment of the physical condition of the body. It holds out the promise of greater physical strength, increased endurance, greater freedom from fatigue, and a condition of well-being that is full of suggestion for the betterment of health."[1] Since Christmas, 1901, I have personally practised thorough mastication and have had many opportunities of observing the result of its practice in others. My interest in the subject has been two-fold: (1) to endeavour to ascertain the explanation of the phenomena presented during thorough mastication, both from an anatomical and physiological point of view; and (2) to make observations in its application of chronic disease.

In Gegenbaur's "Anatomie der Wirbelthiere," p. 90 (Vergleichender), is found: "The bifurcation of the alimentary canal below the soft palate does not depend only on its relations with the epiglottis but also on the condition of the food. The exclusive use of this means of swallowing is only possible with very finely divided food. ...... I have called this way of taking food poltophagy (poltos=masticated, finely divided) and the other psomophagy (psomos=biting)." I believe that this observation of Gegenbaur gives the clue to the explanation of these phenomena. It will be seen that the classical explanation of the first part of deglutition is the description of that part of deglutition in a psomophagic animal. I propose to try to show that though man has obviously a psomophagic faculty he has the "evolution education" and the necessary anatomical structures to enable him to be poltophagic.

---

[1] Physiological Economy in Nutrition, by Russell K. Chittenden, Ph.D., Sc.D., LL.D., p. 474. New York: Fredk. Stokes and Co., 1904.

1. *Some observations on the prominent characteristics of poltophagic and psomophagic animals.*—The horse is a typically poltophagic animal. The soft palate is thick and muscular. Looked at posteriorly (by removal of the vertebræ and opening the pharynx) it will be found to extend downwards centrally well in front of the epiglottis. The opening of the fauces is comparatively small. The epiglottis is conspicuously large with rounded and everted edges. The soft palate forms with its lateral and posterior surfaces a grooved passage on either side leading by the laryngeal furrows to the pharynx, thus very clearly showing how the divided current of food is passed into the pharynx. It may be noted that the horse does not cover its nostrils with water when drinking and that the respirations are not synchronous with movements of suction and swallowing. The œsophagus can be readily felt and exposed by a simple incision. The food (hay or oats) is swallowed in long fusiform semi-fluid masses. A horse is unable to breathe through its mouth, so closely is the soft palate in contact with the tongue and epiglottis.

The dog is an equally good example of the psomophagic type. The soft palate is a thin translucent membrane, consisting of little else than the two layers of mucous membrane, showing a few scattered muscular fibres in the position of the azygos uvulæ, the soft palate apparently only serving as a valve to prevent the passage of food into the nasal fossæ. The opening of the pharynx is comparatively large. The epiglottis is small, pointed, thin, and pliable, being closely in contact with the tongue. The laryngeal furrows are not well marked. The well-known fact that the dog laps water shows that it lacks the power of suction by the soft palate.

2. *A brief description of the human poltophagic apparatus.*—It will be better to divide the mouth cavity into three parts for convenience of description: (*a*) an anterior buccal cavity; (*b*) the buccal passage leading into (*c*), the posterior buccal cavity. (See Fig. 2A, B, and C.)

(*a*) The anterior buccal cavity is the portion of the mouth between the tongue and the parietes of the mouth.

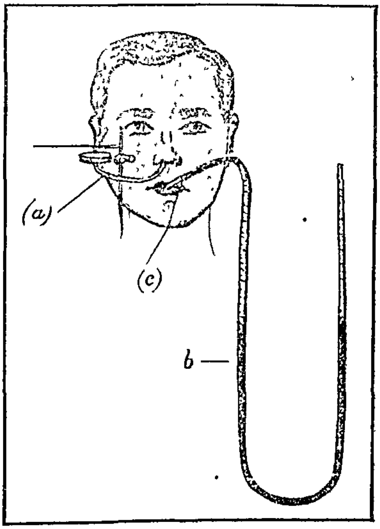
(*b*) The buccal passage, when the tongue is in contact with the hard palate while the mouth is closed, is bounded laterally by the molars of the upper jaw and the pillars of the fauces, below by the tongue as far as the circumvallate papillæ, and above by the hard and soft palate. It will be seen that the passage is long and semilunar in cross section, opening forwards between the tongue and the hard palate and posteriorly into the posterior buccal cavity. The musculature of the tongue is conspicuous for the remarkable complexity of the intrinsic and extrinsic muscles. Their arrangement permits of an extraordinary number of complex movements and changes of shape; thus, parts of the organ are able to execute independent movements. For example, if one lies on one's back it is possible, while holding water in the mouth, to block up the hinder part of the buccal passage and at the same time to move the fore part of the tongue freely in the mouth as in masticating without exciting a swallowing impulse. The central part of the tongue can be depressed either wholly or in parts or gradually from before backwards, making with the tongue and hard palate a sort of valvular opening from the anterior to the posterior buccal cavity. The presence of the taste buds in the immediate neighbourhood of the circumvallate papillæ would afford a means of determining whether a sample of semi-liquid food is in a fit state to pass on to the posterior cavity.

(*c*) The posterior cavity communicates anteriorly with the buccal passage and can be closed posteriorly by the soft palate. It is therefore bounded anteriorly by that portion of the tongue posterior to the circumvallate papillæ, posteriorly by the soft palate, and laterally by the junction of the soft palate and the tongue. In the soft palate is found an arrangement of muscles permitting a variety of movements; thus, the contraction of the palato-glossi, palato pharyngei, and the tensores palati would cause the soft palate to tend to become flattened and the lower border to be applied to the posterior surface of the tongue. The contraction of the levatores palati (while the border is applied to the tongue) would cause the soft palate to be more concave anteriorly and to act as a suction pump.

3. *Some experiments illustrating the functions of the soft palate.*—The most simple illustration of poltophagic and psomophagic deglutitions in man is afforded by two ways in which water can be swallowed; (*a*) it can be swallowed at once by pushing it against the soft palate by the tongue (psomophagy); and (*b*) it can be swallowed more slowly by employing movements of mastication; as soon as the water is warmed it is swallowed by a series of short deglutitions. This is more distinct if anything if the head is held downwards (poltophagy).

The following experiments were made with a view of analysing these movements and especially to demonstrate the functions of the soft palate. In each case one of the nostrils was closed and the other was connected by means of a nosepiece with a Marey's tambour and lever (Fig. 1, *a*) which readily records respiratory movements. A U tube (Fig. 1, *b*) filled with coloured water was used, one of the limbs being provided with an indiarubber tube and a mouthpiece (Fig. 1, *c*).

FIG. 1.



(1) A positive pressure can be produced and maintained (about from 20 to 25 cubic centimetres of water); (2) a negative pressure can be produced and maintained in the same way; (3) rapidly alternating positive and negative pressures can be produced; and (4) from 45 to 50 cubic centimetres of water can be sucked up into the mouth. Note: When the tongue is protruded only from 15 to 20 cubic centimetres can be sucked up.[2] These experiments can be produced: (*a*) During slow inspiration; (*b*) during slow expiration; (*c*) during cessation of respiration; (*d*) during hurried respiration; and (*e*) when the tongue is protruded. The movements of the soft palate consequent on the production of positive and negative pressures were recorded by means of the apparatus shewn in Fig. 2. An instrument of the size and shape of a Eustachian catheter, jointed at (*a*), the moveable portion (*b*) being attached to a thread (*c*), which passes through (*d*) a hollow handle. The instrument is then introduced into the nostril and fixed therein by a clamp. The head is fixed firmly. The thread is attached to a vertically disposed [illegible] a horizontal [illegible] movement of [illegible] movement of

---

[2] When water is sucked up by the lips one can continue hurried respirations till deglutition takes place when it appears to be inhibited till the act of deglutition is completed.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv., Prooemium.

LIVERPOOL INFIRMARY FOR CHILDREN.

A CASE OF MULTIPLE FRACTURES IN AN INFANT.

(Under the care of Mr. R. C. Dun.)

A boy, 15 days old, was taken to the Liverpool Infirmary for Children on account of "crooked legs and a want of power in the arms." He was the first child of a young mother and had been born at full time after a normal labour. Both parents were healthy and there was no history of syphilis or congenital defects on either side. The mother had been in good health and had met with no accident during her pregnancy. She appeared to be very careful with the baby and was positive that he had not fallen or received any injury since birth.

The child was small, pale, and delicate in appearance. On examination of the lower extremities the thighs showed distinct antero-external curvature, most marked upon the left side. A sharp, almost rectangular, inward bend of both legs was present midway between the knee- and ankle-joints causing the soles of the feet to face directly inwards. A hard and apparently bony swelling was felt encircling the shaft of the right femur slightly above its centre. The left femur showed three similar enlargements, one at the middle of the shaft, the others rather more than one inch above and below the first. Both femora were intact. The right tibia was markedly thickened just above the point of bending of the shaft; no abnormal mobility was detected. A slight thickening occurred at a corresponding situation on the left tibia and mobility was elicited at the point of curvature. The upper extremities hung listless by the sides. There was no attempt at voluntary movement and the infant did not appear to suffer pain during their examination. A bilateral club-hand of the ulnar-palmar type was present. The right forearm was normal in appearance but definite antero-posterior movement was obtained at a point opposite the centres of the radial and ulnar shafts. No bony thickening was present. The left forearm showed a slight angular curvature at its mid-point, with similar abnormal mobility, and no callus formation. The radius and ulna on both sides were apparently well developed. Slight inward bending of the right upper arm was evident. The left was straight. Abnormal mobility was present at the centre of both humeral shafts but no thickening was detected. Both clavicles were enlarged and slightly bent forwards at their mid-points. In none of the bones examined was crepitus elicited. No skin cicatrices occurred over the sites of deformity. Examination of the head revealed a soft and yielding condition of the cranial bones with all the sutures widely open. There was no tension suggestive of hydrocephalus and the circumference of the head was only 13 inches. Nothing abnormal was detected about the ribs, the spine, the pelvis, or the small bones of the hands and feet.

An x ray photograph of the trunk and extremities was taken by Dr. Thurstan Holland. It showed bony thickening of both clavicles at their centres, with slight forward curvature. There was an oblique fracture of the right humerus slightly below the middle of the shaft, the line of fracture passing from above and within, downwards and outwards. No callus formation was present. A transverse fracture of the shaft of the left humerus with no thickening or deformity was evident. Transverse fractures of both bones of both forearms at their centres were seen with no callus developed, and there was slight angling at the seat of fracture on the right side. The radius and ulna on both sides were completely formed and all the small bones of the misplaced hands were present. On the right femur an encircling ring of bony callus was evident just above the centre of the shaft. The left femur showed thickening of the upper third of the shaft with a projection of bony callus from its inner aspect. Slightly above the centre of the shaft a ring of newly formed bone similar to that on the right side appeared and below this, again, a second well-developed ring of callus occurred. The lower third of the shaft of the femur from this point down to the lower epiphyseal line was distinctly enlarged. In the leg bones the sharp inward bending of the lower halves of the shafts was evident. On the right side bony callus was present just above the angle of curvature; on the left side an incomplete transverse fracture of both bones was seen with early callus formation.

Definite evidence of the occurrence of 12 fractures was thus obtained. In seven of these firm bony union had taken place 15 days after birth. In four the process of repair had not started and in one it was only slightly advanced. From this it may be inferred that the majority of the fractures took place during birth, or possibly in the uterus before labour commenced, and that the remainder occurred during extra-uterine life. With suitable local splints the fractures of the bones of the upper extremity and the left tibia and fibula united rapidly and without deformity. The curvatures of the bones of the lower extremities remain and will demand subsequent correction. The ossification of the cranial bones progresses slowly. The child has been kept on the breast and has thriven well. He has been under observation for ten weeks and no further fractures have developed. No drugs were given.

Remarks by Mr. Dun.—Such cases of multiple fractures in the newly born are rare. They cannot be placed in the same category with those in which one or more bones are broken, usually at the epiphyseal lines, as a result of severe traumatism during labour or from accidents met with after birth. In the present case the labour was normal and no injury occurred afterwards, while all the fractures involved the shafts of the long bones. These facts, taken in conjunction with the imperfectly developed state of the cranial bones, would indicate the probable existence of some general congenital defect in bone formation. Such a condition has been described under the name of osteogenesis imperfecta or osteopsathyrosis. It is characterised by the occurrence of multiple and comparatively painless fractures of the shafts of the long bones which take place without definite traumatism. Delayed ossification of the cranial bones is a common feature. Under treatment the fractures readily unite, as in the present case. The cause of the imperfect development of bone is not definitely known. It has been ascribed to congenital syphilis, rickets, and nerve disease, but no evidence of any of these conditions was found in the present example, nor was any history of a hereditary tendency to fractures ascertained, although this has been noted in some of the recorded cases. Associated congenital deformities have frequently been present. Whatever may be the cause giving rise to this condition of congenital fragility of bone it is certain that very slight traumatisms are sufficient to produce fractures in those cases in which it is present. As examples may be mentioned such slight forces as normal uterine contraction, the passage of the fœtus through the maternal passages during normal labour, muscular action on the part of the fœtus or infant, and the ordinary careful handling of the child.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

A Fatal Case of Typhoid Fever with Lobar Pneumonia due to the Bacillus Typhosus.—The Operative Treatment of Cases of Fracture of the Astragalus.

A meeting of this society was held on May 12th, Dr. Frederick Taylor, the President, being in the chair.

Dr. Sidney P. Phillips and Mr. B. H. Spilsbury recorded the case of a patient, aged 20 years, who came under observation on Dec. 2nd, 1904, suffering from typhoid fever at about the tenth day. The temperature was high—105·6° F.; the cutaneous eruption was just commencing to appear; and there were evidences of a patch of pneumonia at the right apex and of hepatisation of the whole of the lower lobe of the left lung. Four days later there were signs of resolution of the pneumonia of the right apex but the patient's condition did not improve The abdominal symptoms of the typhoid fever were moderate in severity and tended in due course to decline but the pneumonia at the base of the left lung showed no signs of resolution The tubular breathing persisted and the fever, cyanosis, and dyspnœa became extreme Toxæmia and failing pulse supervened and death occurred on Dec 11th The necropsy showed numerous typhoid ulcers in the small intestine in various stages, but none perforated, and a few small ulcers in the ascending colon The lower lobe of the left lung was in a state of red hepatisation and scattered throughout it were small white nodules which to the naked eye appeared to be tubercles They were found by Mr Spilsbury in the pathological laboratory of St Mary's Hospital to be minute abscesses, in which were large masses of organisms—in some minute cocci retaining Gram's stain, and in others bacilli which had the morphological appearances and staining reactions of the bacillus typhosus The remainder of the lung showed the microscopical characters of delayed resolution of a croupous pneumonia No pneumococci or tubercle bacilli were to be found in the lung The lung and the microscopic slides were exhibited at the meeting Dr Phillips, in commenting upon the case, pointed out that pneumonia occurring in typhoid fever at any period in its course was almost always due to the pneumococcus or the staphylococcus Very few cases were on record where it was due, as in this case to the specific bacillus of typhoid fever Polguère of Paris had described a very similar case In its clinical manifestations the case now recorded bore more the general characters of a case of pneumonia than of a case of typhoid fever, the pulmonary symptoms predominating The onset of the pneumonia was early in the course of the typhoid attack, its development was rapid, and its resolution was very much delayed These were points which were said by Polguère to be characteristic of typho pneumonia —Dr E W GOODALL referred to the large amount of labour necessary in working out such a case as that just described Lobar pneumonia was not common in the course of typhoid fever and generally occurred late in the disease He thought that a typical lobar pneumonia was rare in the early stages of typhoid fever The question of the primary infection of the lung or the kidney by the typhoid bacillus was one of great interest and he asked Dr Phillips whether he had ever seen the lungs primarily affected by the bacillus typhosus —Dr HERBERT S FRENCH said that although he was not able to add to Dr Phillips's any other case in which typhoid bacilli had actually been found in the lung, perhaps the following notes might be of interest in that they recorded the pneumonic onset of typhoid fever in several members of the same family The early diagnosis was pneumonia in all the cases, whilst the ultimate [illegible] fever The notes of the cases [illegible] different persons it was onl[illegible] came to be indexed that their [illegible] A woman was taken ill with a malady which was regarded as influenza at first and then as lobar pneumonia She was treated at home by her own medical man The duration [illegible] was [illegible] out [illegible] the end of October, 1901 During her illness she was ministered to by her eldest daughter, aged 11 years On Oct 25th, 1901, the daughter was taken ill with what seemed to be acute pneumonia Her chest was poulticed and three days later she was sent to Guy's Hospital as a case of lobar pneumonia She was under the care of Dr G N Pitt until she went out cured on Nov 26th Her lung signs were bronchial breathing, consonating râles, and pectoriloquy all over the left lower lobe, together with rhonchi over the rest of her lungs On admission her respiration rate was 68, her temperature was 105° F, and her pulse was 124 No crisis came Some days later her spleen, not palpable at first, became enla[illegible] enteric fever suggested itself and was confirmed [illegible] Widal's test There was no leucocytosis, the count [illegible] 14,000 per cubic millimetre The course of the pyrexia was typical of uncomplicated typhoid fever and she recovered completely On Nov 21st, 1901, four weeks after the daughter had been taken ill her brother, aged nine years was admitted to Guy's Hospital under the late Dr J W Washbourn, with a precisely similar condition to that of his sister The left lower lobe was dull and on auscultation bronchial breathing, pectoriloquy, and crepitations were heard over it, whilst there were rhonchi scattered over the rest of the chest There was no leucocytosis (7187 per cubic millimetre) The respiration rate was 52, the temperature was 103° F, and the pulse rate was 120 There was no crisis The lung signs abated but the pyrexia continued The spleen was subsequently palpated, typhoid fever was diagnosed and confirmed by Widal's test The boy got well The course of the disease was exactly like that of uncomplicated typhoid fever On Nov 29th, 1901, a sister to the above, aged four years, was admitted to Guy's Hospital also with crepitant râles all over the left lower lobe The condition and the course were precisely similar to those in the brother and the sister Widal's test was positive The child got well It would appear probable that the mother's "pneumonia and acute phthisis" were also pneumonic typhoid fever The pneumonia in these cases was not proved to be due to the typhoid bacillus, but even in 1901 when these cases occurred, Dr Washbourn gave it as his opinion that, had the patients died, typhoid bacilli would have been found in the pneumonic lung Fortunately, the three hospital cases lived, being children, there was no sputum, there was no clinical ground for needling the chest, so that there was no means of investigating the bacteriology of these lungs Nevertheless, the occurrence of four consecutive cases of pneumonia in one family, in three of which typhoid fever was proved by Widal's test, at least suggested that they might have been pneumonia due to the typhoid bacillus The temperature charts were those of typhoid fever pure and simple, and not of pneumonia and typhoid fever, such as was sometimes seen When ordinary lobar pneumonia occurred in a patient who [illegible] e [illegible] d [illegible] e [illegible] chart, the point of onset of the pneumonia and the crisis a pneumonia chart superposed, as it were, upon a typhoid fever chart This was not the case in the present instances To judge by the charts alone they could not detect anything but typhoid fever In none of the three cases examined in the hospital was there leucocytosis, a point which was also, perhaps, suggestive of the entire affection having been typhoidal —Dr F H HAWKINS expressed the belief that pneumonia was uncommon in cases of typhoid fever and in 100 cases recently investigated it had only been present in 1 per cent —Dr W PASTEUR said that the evidence that a pneumonia was due to the bacillus typhosus could only be obtained by careful examination of the lung in fatal cases His impression was that acute pneumonia in the course of typhoid fever was rare He referred to a case in which a meningitis was due to the bacillus typhosus —Dr PHILLIPS replied

Mr J HUTCHINSON, jun, and Mr HUGH LETT, in a paper on the Operative Treatment of Cases of Fracture of the Astragalus, stated that in various instances of impacted fracture of the astragalus the foot remained in equinus combined with varus so that its functions were greatly impeded, the patient being unable to walk with the heel and the toes touching the ground Where manipulation under anæsthesia failed to correct the impaction (proved by the x rays) Mr Hutchinson and Mr Lett advocated excision of the fractured bone At the same time they rejected the teaching of M Ombrédanne that all cases of fracture of the astragalus should be treated by excision, which could only be required in the exceptional instances of persistent deformity It was suggested that in cases of dislocation of the astragalus the external malleolus should be chiselled through at its base to facilitate the reduction A series of eight cases of fracture of the os calcis was discussed, the x rays proving that comminuted fracture of the body of the bone was the most common form, due to falls from a height Widening of the os calcis, a band of deep ecchymosis beneath the malleoli, and the appearance of flat foot were the chief signs apart [illegible] Although several [illegible] t could walk well, [illegible] the cases up after [illegible] nce, operative interference in [illegible] —Mr W G SPENCER said that [illegible] of the very greatest service in [illegible] had led to a falling off in the [illegible] res which was so important [illegible] supervened He thought that there should be no delay in putting up a fracture and too much stress was laid on the importance of getting a skiagram

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Word Blindness.—Treatment of Disease by Intravenous Injections.

A MEETING of this society was held on May 3rd, Professor JOHN CHIENE, the President, being in the chair.

Dr. BYROM BRAMWELL exhibited two cases of Leukæmia after treatment by the x rays. 1. The first occurred in a woman, aged 28 years, who had been admitted to the Royal Infirmary two months previously. She suffered from well-marked spleno-medullary leukæmia, the spleen being much enlarged and the white blood corpuscles increased to 450,000 instead of the normal 5000 to 10,000 per cubic millimetre; 41 per cent. of these were myelocytes. Her temperature was normal but this underwent a notable rise after application of the x rays. Later, however, it slowly fell. For some days subsequently to this treatment nothing was noted but gradually a marked improvement in the patient's condition occurred. At the present time her spleen had undergone a distinct diminution from its former hypertrophied condition, the white blood corpuscles had fallen in number to 28,000, and her general health had much improved; 48 per cent. of the white corpuscles were still of the myelocyte variety. 2. The second case occurred in a boy the subject of lymphatic leukæmia; the white blood corpuscles amounted to 300,000 and the majority were large lymphocytes. After application of the x rays there was also a rise in his temperature accompanied by inflammatory reaction over the spleen. The number of leucocytes fell to the normal (8000 per cubic millimetre) under x ray treatment but a general improvement did not take place (although the spleen underwent a reduction in size), and the patient died. The prognosis of such cases under x ray treatment could not be stated. In many of the recorded cases an injurious inflammation took place over the spleen and had even resulted in death.

Dr. BYROM BRAMWELL also exhibited a most remarkable case of Gout. The patient, a man, aged 52 years, had been under the care of Sir Dyce Duckworth for some time. The patient's habits had never been such as to lead him to contract gout. On the other hand, he had developed the disease 28 years ago while living in the wilds of Australia. His first acute attack began at that time and he had suffered from two to three of these every year since. The urine had been albuminous ever since the disease commenced. The number of tophi was quite remarkable and Sir Dyce Duckworth stated that he had never seen so striking an example of gout. There were enormous masses over the metacarpals, the olecrana, the patellæ, and over the heads of the tibiæ and the fibulæ. Discharging ulcers were present on the hands and the feet, yet the patient's general condition was good. Surgeons did not recommend any operative interference in such a case.

Mr. J. M. COTTERILL showed a male patient, aged 40 years, suffering from Multiple Chondroma and Chondro-sarcoma. In early life the chondromata began to grow from the ends of the long bones. The majority had now either ossified or calcified. A very large one over the left scapula had existed for 20 years. It grew from the ribs and left the scapula freely moveable. The tumours were mostly symmetrical. An enormous tumour had, however, grown during the last five months from the right ilium and was undoubtedly sarcomatous. As operative measures were impossible x ray treatment was being given to this chondro-sarcoma and the patient thought that already the tumour was softer and more moveable.

Mr. H. ALEXIS THOMSON showed a case of Extroversion of the Bladder after Transplantation of the Ureters into the Rectum (Peters's Operation). The patient was a boy, aged nine years. The absence of the symphysis pubis made him waddle in walking. The ureters were transplanted extra-peritoneally and he had made remarkable progress, being now able to hold his urine for eight hours. The urine was rarely free from fæcal matter but no symptoms of ascending septic infection had shown themselves.

Mr. J. V. PATERSON and Dr. EDWIN BRAMWELL communicated a paper on two cases of Word Blindness. In the first case, that of a man, aged 63 years, there were complete word and nearly complete letter blindness. Numerals were read much more readily than letters. Writing was greatly interfered with, the patient being able to write correctly only about one-half of the letters of the alphabet. Right homonymous hemianopsia was present as well as some rigidity of the right arm and leg following a hemiplegia. Sensation was unimpaired, intelligence remained good, and speech quite unaffected. Blocking of the left posterior cerebral artery was thought to be the most probable explanation of the symptoms which had existed for two and a half years. The second case was that of a man, aged 64 years, who was under treatment for cirrhosis of the kidney and chronic bronchitis when it was found that he had a right homonymous hemianopsia and word blindness. The patient was an intelligent man, although his memory was very defective. He was right-handed. He understood perfectly everything said to him and spoke fluently. There was very pronounced word and letter blindness. He was able to read figures very much better than letters. Writing was very little interfered with. There was no hemiplegia or hemianæsthesia. The patient died with uræmic symptoms. At the necropsy a large area of softening was discovered corresponding to the distribution of the posterior cerebral artery. The cortex in the region of the angular gyrus was not involved.

Dr. THOMAS W. DEWAR (Dunblane) read a paper entitled "A Plea for the Recognition of the Treatment of Disease by Intravenous Injections." He said that the honour of first imagining such a thing to be possible rested with Sir Christopher Wren and detailed his first attempts, in 1665 or 1669, at which the Hon. Robert Boyle and Wilkins assisted, mentioning that to Boyle belonged the honour of having first suggested its application to human beings. The work done in the following centuries was then narrated. About the last quarter of the nineteeth century a change came over the method owing to the manufacture of fine hollow needles and improvement in the apparatus. This enabled the operator to administer with certainty, safety, and practically no injury to the vessels 100, 200, or 300 injections, whereas formerly two or three might end in obliteration of the lumen, phlebitis, thrombosis, or suppuration. Dr. Dewar's experience of intravenous injections convinced him that obliteration of the tube was due to the solutions introduced to a much greater extent than to the wound of puncture; that if a large volume was to be introduced the needle must have a considerable calibre and the pressure be great. In no case should the needle after loosening the tourniquet fill the lumen of the vessel unless the injection be very small. In 1890 Baccelli injected with quinine 30 patients who were suffering from severe malaria and all recovered. In 1893 Landerer injected cinnamate of sodium and claimed good results in pulmonary tuberculosis. This treatment seemed to be powerful in early cases but was inapplicable in cases with vomicæ or mixed infection. In 1899 Gautier injected cacodylate of sodium and in 1896 Ernest Lane injected 76 syphilitic patients with a 1 per cent. solution of cyanide of mercury with an apparent cure in 50 cases. Such diseases as malignant pustule, erysipelas, ulcerative endocarditis, pneumonia, cerebro spinal meningitis, and so on, were reported as having yielded to this method of treatment. The most impressive feature in the whole history of the subject was the extraordinary vitality of Wren's original idea. For 250 years it had possessed the minds of medical men. Despite difficulties, failures, and opposition it had held its own and had steadily gained in power. The main grounds alleged against this treatment were (1) its restriction to the venous distribution; (2) injury to veins (Dr. Dewar had never met with embolism and rarely with thrombosis and had patients with good veins after 200 and 300 injections); and (3) the negative results of laboratory experiments on inoculated animals. In this department Baccelli, Behring, Cash, Washbourn, Fortescue-Brickdale, and others had worked and their results were incontrovertible for the animals all died. Dr. Dewar, however, did not think that they had any right to argue that the results obtained clinically were inaccurate or that there was no future for intravenous work in the human subject. A case of marked oral sepsis was narrated. Streptococci were present in large numbers in the discharge and antistreptococcic serum was administered but this, as well as large doses of quinine, had no effect on the condition. A single intravenous injection of formic aldehyde in physiological solution cured the patient almost immediately. A second instance was a case of tuberculous abscess of the lung in a patient with acute pulmonary tuberculosis. The cure by intravenous injection was absolute and rapid. Tubercle bacilli, sputum, and cough all disappeared. In a disease so varied as

pulmonary tuberculosis, so merciless in its progress, so defiant of all treatment, it was permissible to try anything and to cling to any method which seemed to impart a sense of control, even although the results were neither rapid nor brilliant Dr Dewar took exception to two statements frequently made 1 "The constant phenomenon of the self-limitation of tubercle ' He did not know of any such benignant quality clinically If tissue resistance were strong progress was arrested or slow, if weak, progress was rapid 2 That the presence of apical scars or nodules was proof of the curability of pulmonary tuberculosis In a former paper Dr Dewar had given his experience of the progress made in arresting pulmonary tuberculosis by intravenous injection of iodoform and he stated that tubercle bacilli had now disappeared from the expectoration in Cases 3 and 4 and that Case 4 had passed a medical board Of the nine cases reported in the second paper four were now free from tubercle bacilli and the others were all doing well As regards the *modus operandi* of iodoform in such cases three suggestions might be made 1 That it acted as a germicide It might act powerfully when introduced in very fine division to the minute capillaries of the lung and deposited at the very *seat of the disease* 2 *If this directly destructive effect* was not likely, and he admitted that it was difficult to imagine
one quarter or one h
a human body doing
the cells, the micro
phagocytosis at the
Iodoform might eve
3 It was possible t
and resulted in the production of bodies even more powerfully destructive to germs Iodoform in solution of ether or chloroform was easily oxidised by oxygen in the air in the presence of sunlight, x rays, or radium A natural change would be that two atoms of iodine in iodoform would be substituted by one atom of oxygen, so producing iodo formic aldehyde, a body as yet not isolated chemically but theoretically more powerful than formic aldehyde If this iodoformic aldehyde parted with its atom of iodine and took up hydrogen nascent formic aldehyde would be formed *in situ* and so a germicide of enormous power would act on the tubercle bacilli The liberated nascent free iodine in the circulation was also a valuable asset It could produce new organic iodo substitution compounds with other bodies from which the iodine could be liberated again by a similar cycle of operations, so that the iodine would be alternately free and combined It was therefore possible that the iodine (which formed $\frac{3}{3}\frac{3}{4}$ths by weight of iodoform) might exert its bactericidal action at the seat of disease If iodoform was not all oxidised when in ethereal solution the oxygen in the red blood cells was able to do as much as the free oxygen + radiant energy The iodoform molecule was still capable of being transformed by reduction into methylene iodide (CH_2I_2 + HI), giving again HI which might act upon organic iodo substitution products, setting free iodine The methylene iodide might react upon water or be itself oxidised to produce formic acid
mical cycle
e processes
the action
of iodine in weak alkaline solutions might take place In such circumstances it formed iodides and iodates, which being acidulated would again liberate free iodine That excessively minute quantities of certain bodies are capable of profoundly changing other bodies was now well known Thus one part of sulphate of copper to 100 000 parts of water would destroy completely the organisms of cholera or typhoid fever in three or four hours Such an infinitesimal dose would be absolutely innocuous to the human system if administered orally or intravenously Dr Dewar acknowledged that the treatment of pulmonary tuberculosis by intravenous injection was not easy at first nor was the improvement always immediate It required care, patience, and a constant self restraint It was impossible to estimate the number of injections which might have to be given, thus success depended on preserving the veins It was Dr Dewar s custom to continue treatment for some time after the disease had become quiescent and the patient apparently well To arrest the pernicious activity of the tubercle bacillus well established in its host must of necessity be a slow and laborious proceeding but when the issue at stake was considered the minute observance of detail and weary monotony of treatment sank into insignificance —Dr R W PHILIP, Dr V SHAW, Dr T M BURN MURDOCH, Dr G LOVELL GULLAND, and the PRESIDENT took part in the discussion which followed

---

EPIDEMIOLOGICAL SOCIETY —A meeting of this society was held on May 5th, Dr B A Whitelegge, the President being in the chair —Dr A Newsholme opened the adjourned discussion on Dr G S Buchanan's paper on the Spread of Small pox around Small pox Hospitals in Relation to Aerial Convection He criticised the conclusions as to the outbreaks at Purfleet, &c and challenged the denial of communication between the ships and the shore as incapable of proof He showed that, as regards Liverpool, circles drawn around the centres of greatest aggregation of spots gave results in no way corresponding with those of circles drawn round the hospitals He disputed the value of Dr Buchanan's method of calculating incidence by the percentage of houses invaded and showed that by taking cases it would appear to be safer to reside within a quarter than half a mile, and within than beyond a mile, of a hospital, and so taken Dr J C Thresh's figures showed the like absence of gradation save in the converse of what it was sought to prove Nor could he admit *the contention that negative evidence was of no value* even if all the same conditions were present 20 per cent of the consumers of a suspected milk would be a minority, but their contracting scarlet fever would be deemed positive evidence, unaffected by the negative evidence of the remaining 80, and in 80 per cent of small pox hospitals the Local Government Board could find no evidence of aerial convection On Dr Buchanan s hypothesis the wind carrying the infection must have always been east in the case of one hospital and west in that of the other He did not deny the fact of aerial convection of small pox any more than of scarlet fever or other infectious diseases, but it was in respect of small pox only that it was claimed as the dominant factor Personal infection, direct or by means of fomites, should be excluded before its spread was ascribed to aerial conveyance and Dr Thresh admitted the occurrence of surreptitious communication, though Dr Buchanan denied it Negative evidence must always be rigidly tested and secondary cases need not be in the same house Looking at the distribution of small pox on the eastern borders of the metropolitan area it would have been quite possible for the epidemic at Purfleet and Grays to have broken out had there been no ships in the river If personal communication must be invoked to explain the spread at great distances why not in the vicinity also The areas of the zones and *cæteris paribus* the populations were as the squares of the distances, if therefore the incidence decreased directly it would be relatively greater However conveyed, the same laws would govern the gradation of incidence so that this proved nothing, and in no case had the personal mode been excluded or the aerial proved Dr. Buchanan insisted on the constant detection of cases at Purfleet and the paucity of missed ones but if found these were not missed Dr Buchanan alleged as evidence of aerial convection the fact of the epidemic around the hospital but the first cases occurred before the hospital was opened and the subsequent ones appeared around the
origin where there was no hos-
pital r Newsholme s circles as
mere uite needless to prove that
hospitals spread the disease At Oldham he found the proportion of houses attacked in the successive zones around a common lodging house in the centre of the town where a case had occurred to be 4 7 1 5, 0 35, and 0 42 and around the hospital 0 42, 0 43, 0 53 and 0 22 While there were many acute cases in the hospital two outbursts of untraced cases were observed in January and February numbering respectively six and 21 During the former the wind was variable but prior to the latter it blew for a fortnight from the hospital towards the locality of the outbreak which could not be traced to any other source At Manchester there was on one side of the Monsell Hospital a brook not crossed by traffic but a number of cases of untraced origin appeared simultaneously on the other side after the wind had been blowing in that direction, and both there and at Oldham the removal of acute cases
ion from the hospitals —Dr
e doubted the influence of
s whether it was due to aerial
t operated elsewhere It had
been ascribed to 'acute" cases but all were acute at first, and the unvaccinated were *highly, in fact most, infectious*

during scabbing and convalescence. Small-pox was intensely infectious, and, according to Mr. W. H. Power, the mildest cases and concealed cases contributed largely to its spread. Dr. Buchanan had given the evidence on both sides, though insisting most strongly on aerial convection, but Dr. R. J. Reece had from first to last absolutely ignored all other factors and conditions, otherwise his report would have been convincing. He admitted the accuracy of Dr. Reece's maps but not his conclusions, for if zones were drawn round a hospital that had not been used for small-pox for many years the district would be seen to have suffered more severely and the gradation to have been more marked than around the small-pox hospitals. In Liverpool concealment was practically unknown, false information being penal under local Acts. According to Dr. Reece, the small-pox incidence was heavier around the Fazakerly Hospital than around that of Priory-road, though the former site, consisting of an open space of 130 acres to which further additions had been made, was pronounced by three Local Government Board inspectors to be the best possible, but Dr. Reece suppressed all evidence against his contention. Priory-road was the least desirable but one case only occurred in *the quarter-mile zone with a population of 500. In the* vicinity of Park-hill hospital 12 distinct outbreaks occurred before the hospital was opened and nine after the reception of patients. Why, he asked, should these be ascribed to the influence of the hospital, while the 12 were evidently independent of it? Besides, four of the nine were proved to have been infected elsewhere. In fact, considerably more than half the cases occurring within a mile of one or other of the hospitals were traced to infection in other places, 54 had been treated as chicken-pox, others travelled in trams, worked in shops and factories, attended the out-patient departments of hospitals, or roamed the streets, but all who resided within a certain distance of a hospital were referred by Dr. Reece to its influence and ascribed by him to aerial convection, even when his attention had been called to the fact that they had been clearly proved to be members of groups or series of cases of simultaneous or consecutive infection from known sources. His maps of the Fazakerly area showed a maximum of cases several months after the maximum occupation of the hospital, and, indeed, when it had been for some time empty and aerial convection could no longer be entertained.—Dr. J. C. McVail remarked that even Dr. Newsholme agreed that small-pox hospitals should not be placed in thickly peopled districts but he (Dr. McVail) argued that negative instances did not disprove the fact of hospital influence any more than the occurrence of cases of small-pox or scarlet fever in slums without the diseases spreading proved them not to be infectious. Referring to Dr. C. B. Ker's experience of Edinburgh, he pointed out that the inmates of schools and asylums were not fairly comparable with the general population, being most recently vaccinated or of an age at which susceptibility was greatly lessened. Fever hospitals had rarely been found a danger to the locality, nor did small-pox appear to spread when a hospital was occupied by convalescents only; indeed, where the cases were of the ordinary character aerial convection did not always follow. Dr. G. Reid had been unable to prove it in any one of the 17 hospitals in Staffordshire.—The President said that all were agreed as to aerial convection at short distances, for all infection other than by inoculation or ingestion was through the air, but every outbreak in the crowded quarters of towns afforded instances of aerial convection, of personal infection, and of the non-extension of the disease even from virulent and concealed cases. It was most reasonable and safest to admit and to provide for every form of communication, of which aerial convection was one, in all diseases, though perhaps playing a more important part in small-pox than in others and, judging from the analogy of other particulate matter, by no means confined to comparatively short distances.—At the suggestion of Dr. McVail it was agreed that members who had been unable to take part in the discussion might send in writing any remarks which they might wish to make, with a view to their reproduction in the Transactions.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting *of this society was held on May 11th, Dr. William Alexander,* the President, being in the chair.—Dr. George H. Burford showed a specimen of Ectopic Gestation occurring simultaneously in both Fallopian tubes removed at the end of the second month of pregnancy from a multipara, aged 33 years. There was a clear history of regular menstruation for three years antecedent to the present gestation. Examination showed the parts removed to consist of two tubal sacs, each with the corresponding fœtus, from the right and left side respectively. The patient made a good recovery.—The President remarked that the condition was a very rare one and that he did not remember having seen a similar specimen.—Dr. H. M. Macnaughton-Jones showed: (1) specimens of Double Salpingo-ovaritis, the result of gonorrhœa; and (2) the Contents of a Uterus removed for Suppurative Endometritis, the result of gonorrhœa.—Dr. Burford and Dr. James Johnstone communicated a paper on Transfusion, Subcutaneous and Intravenous, in Gynæcological Practice. Dr. Johnstone dealt with the question from the historical, physiological, and pathological aspects. He said that when a large quantity of blood was withdrawn from the circulation the blood pressure fell but might soon regain its normal height owing to increased peripheral resistance due to the action of the vaso-motor centre. It was only after very severe hæmorrhage that the pressure fell rapidly and death would follow unless means were taken to prevent failure of the circulation. *Both hæmorrhage and shock were marked by a* fall in blood pressure, due in the former case to depletion of blood and in the latter to diminished peripheral resistance. The objections to using blood in transfusion were (1) the difficulty of obtaining it quickly and in sufficient quantity and (2) the difficulty of preventing it from clotting. Normal saline solution, on the other hand, was readily prepared, the process of transfusion was free from danger, the quantity might be varied at will, and the process might be repeated if necessary.—Dr. Burford then gave a report of 25 cases, post-operative and puerperal, in which transfusion of normal saline solution had been employed. In the post-operative cases where the indications were those of shock or hæmorrhage the patients almost uniformly recovered. Where the indications were those of sepsis the transfusion was uniformly of no avail. Among the obstetric cases, one of urobilinuria during pregnancy was cited where transfusion also proved useless, and one of puerperal hæmorrhage during acute mania where the procedure was successful. The quantity of fluid varied, being in one instance as much as seven pints given by the intravenous method at one sitting. An instrument for intravenous or subcutaneous transfusion was demonstrated.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 4th, Mr. G. Morgan, the President, being in the chair.—Dr. W. J. Rowland showed a boy, aged 12 years, with Congenital Heart Disease, and the heart on the right side of the chest; also a case of Tachycardia brought on by the use of Sandow's exercise.—Dr. D. G. Hall showed a case of Infantilism, aged 25 years, suffering from splenic leucocythæmia; also a case of Bronchiectasis with marked pulmonary arthropathy.—Dr. Walter Broadbent showed a woman, aged 55 years, suffering from Progressive Bulbar Paralysis; also a child with Double Congenital Dislocation of the Hips.—Dr. E. Mackey showed some Hydatid Cysts passed by the Urethra by a man with a tumour in the left hypochondriac region. He discussed the treatment, recommending turpentine. He also showed specimens from a case of Broncho-pneumonia, Ulcerative Endocarditis, and Meningitis, all caused in succession by the staphylococcus pyogenes aureus.—Mr. A. H. Buck read a paper on Appendicitis, recommending removal of the appendix after any attack, however slight. He remarked on the varying position of the appendix, from high up in the right loin down to Douglas's pouch and even to the left iliac fossa. He emphasised the importance of a rectal examination in all suspected cases. He discussed the use of blood examinations. His treatment was to put the patient to bed and to give a dose of castor oil and opium at once, to give a fluid diet, to apply hot flannels to the abdomen, and to use enemata; if not better, to operate on the third day but if possible to leave the operation for three weeks, when an incision from one to two inches long would suffice.—The paper was discussed by the President, Mr. C. H. Bryant, Dr. Broadbent, Mr. T. J. Verrall, and Mr. H. H. Taylor.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on May 10th, Mr. *E. F.* White, the President, being in the chair.—Mr. W. Sampson Handley gave a lantern demonstration on the Pathology and Treatment of Cancer of the Breast. He brought forward evidence to show that cancer of the breast was disseminated mainly by actual cancerous growth along the fine lymphatic vessels—a process to which he had attached the name "permeation." The importance of this process had escaped notice because after a time the cancerous lymphatics were obliterated by "perilymphatic fibrosis," an inflammatory process which destroyed the cancer cells and led to the substitution of a fibrous cord for the original lymphatic. Nodular metastases at isolated points appeared to arise from the local failure of this curative process. In discussing visceral dissemination Mr. Handley drew especial attention to the frequent occurrence of invasion of the abdomen by direct cancerous infiltration of the abdominal wall in the epigastric angle, a point where the parietes were especially thin and weak. He deprecated the extreme removal of skin practised by some operators but advocated wide removal of the deep fascia, especially in the epigastric region. His remarks formed a brief summary of the Hunterian lectures on the same subject which recently appeared in abstract in THE LANCET.[1]

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 5th, Dr. Adolph Bronner being in the chair.—The following cases, pathological specimens, &c., were shown:—Dr. A. E. L. Wear: Uterus removed by Vaginal Hysterectomy for Early Malignant Disease.—Mr. E. Ward: Carcinoma of the Rectum, with a Secondary Nodule just above the growth.—Mr. B. G. A. Moynihan: (1) Papillomatous Ovarian Cysts, four specimens; and (2) Dermoid Cysts, Bilateral; one of the cysts had a twisted pedicle and a broad omental adhesion was also twisted.—Dr. W. Bertram Watson and Dr. A. G. Barrs: A case of Widespread Ulceration involving skin and connective tissue of tuberculous origin, with complete recovery.—Dr. E. F. Trevelyan: (1) A specimen showing an old Apoplectic Cyst in the Pons; and (2) a case of Chorea in a boy, aged 14 years, complicated by severe paralysis, during which the choreic movements at first disappeared but subsequently returned.—Dr. Trevelyan and Mr. H. Littlewood: A case of Spastic Paraplegia in which the obturator nerves were divided for the relief of severe spasm with marked relief.—Dr. H. de C. Woodcock and Dr. Trevelyan: A Brain from a case of Masked Tuberculous Meningitis complicating Pulmonary Tuberculosis.—Dr. J. B. Hellier: (1) Sellheim's Obstetric Phantom; and (2) Ruptured Uterus removed by Hysterectomy.—Dr. T. Churton and Mr. Littlewood: Scirrhous Cancer at the Junction of the Pancreatic and Biliary Ducts.—Mr. Littlewood: (1) Specimen of an Enlarged Prostate associated with Calculus; (2) five specimens of Cholecystectomy; and (3) Chronic Salpingitis simulating Appendicitis.—Dr. W. H. Maxwell Telling: A case of Diffuse Sclerodermia complicating Raynaud's Disease and following Amputation of the Breast.—Mr. R. Lawford Knaggs: (1) Necrosis of the Clavicle (specimen and patient); and (2) Penis and Urethra, including the Prostate, removed for Carcinoma commencing at the Bulb.—Mr. G. Constable Hayes (with Mr. W. H. Brown): A case of Extensive Tuberculous Disease after Treatment with the X Rays.—Dr. Barrs read a paper on Supraclavicular Adenopathy and its Significance, with cases.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—The closing meeting of the session of this society was held on May 8th, Professor R. Muir, the President, being in the chair.—Dr. J. Walker Downie showed as a fresh specimen a Thyroglossal Cyst and a Simple Thyroid Cyst removed from the same patient. Microscopic sections were shown by Dr. J. H. Teacher.—Dr. Teacher read, for Dr. W. L. Reid, the history of a Large Solid Tumour of the Ovary and demonstrated the tumour and sections prepared from it. The patient was 83 years of age; the tumour was noticed five and a half years ago. Operation was undertaken on account of rapid increase of the growth and the development of ascites within the last six months. The patient made an excellent recovery. The tumour weighed 16 pounds 2 ounces. Part of it showed the structure of a hard fibroma but the rest—the larger portion—was spindle-celled sarcoma.—Dr. J. G. Connal read notes of, and showed Sections from, a case of Epithelioma of the External Auditory Meatus. The patient was an old man. Radical operation was out of the question and the patient returned home, where he died somewhat unexpectedly with symptoms suggestive of septic mischief within the cranium. There was no post-mortem examination. Sections of material removed for diagnosis showed the structure of squamous epithelioma. A remarkable feature was the absence of pain.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The last meeting of the session of this society (a clinical evening) was held on May 10th.—The following were some of the cases shown:—Dr. J. O. Symes: A case of Acute Rheumatoid Arthritis.—Dr. Carey P. Coombs: An infant with an Abdominal Tumour.—Dr. F. H. Edgeworth: (1) A case of Head-nodding and Nystagmus; and (2) a Cretin showing the result of Thyroid Treatment.—Dr. J. J. S. Lucas: (1) A case of Macroglossia; and (2) a case of Unexplained Œdema of the Legs.—Dr. W. Kenneth Wills: (1) A case of Linear Nævi; (2) Lupus cured by the X Rays; (3) Adenoma Sebaceum treated by High-frequency Spark; (4) Symmetrical Dystrophy of the Nails; and (5) Rodent Ulcer cured by the X Rays.—Dr. H. Waldo: (1) A case of Tuberculosis Cutis (generalised); (2) a case of Tinea Circinata; (3) a case of Lupus Vulgaris; and (4) a case of Chiropompholyx.—Mr. F. R. Cross: Some cases of Orbital Tumour.—Mr. J. Paul Bush: (1) A case of Post-pharyngeal Abscess; and (2) a case of Pyonephrosis of 11 years' standing.—Dr. J. A Nixon. A case of Multiple Nævi with Pigmentation.—Dr. J. Michell Clarke: A Lesion of the Fifth Cervical Root.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on May 5th, Mr. Charters J. Symonds being in the chair.—Dr. Pinkus of Warsaw, in the absence of Dr. Heryng, exhibited the workings of a New Inhaler.—Sir Felix Semon showed an Atomiser for the application of fluid vaseline to the mucous membrane.—Dr. H. L. Lack showed an interesting case of Angioma of the Palate and Dr. R. H. Scanes Spicer one of Osteomyelitis of the Frontal Bone.—Mr. Symonds showed a case of Total Extirpation of the Larynx.—Dr. H. J. Davis showed a case of Ulceration of the Pharynx associated with left facial paralysis in a man, aged 47 years.—Dr. J. Dundas Grant showed a case of Ulcer of the Pharynx which, in spite of its gummatous appearance, was considered to be epithelioma.—Cases were also shown by Dr. J. Donelan, Mr. P. R. W. de Santi, and Mr. E. B. Waggett, that shown by the last named gentleman being a Bleeding Polypus of the Septum in a boy.

Reviews and Notices of Books.

A Student's Text-book of Zoology. By ADAM SEDGWICK, M.A., F.R.S., Tutor of Trinity College, Cambridge, &c. With 333 figures in the text. London: Swan Sonnenschein and Co. 1905. Pp. ix.-705. Price 21s.

THIS, the second volume of Mr. Sedgwick's text-book, deals with vertebrates and with amphioxus only. The rest of the chordata (tunicates, and so on) will in due course be treated of in a third volume. Consisting as the volume does of so many pages it will be inferred, and correctly inferred, that the author's treatment is fairly exhaustive. There is all the information that the student, and even the advanced student, requires about the anatomy and the classification of vertebrated animals. Moreover, all the salient facts are illustrated by numerous figures in the text. We know of no English text-book of vertebrates that is so full as that which we notice in this column.

Mr. Sedgwick carefully guards himself in his preface from criticism against what might, he thinks, appear to be anti-evolutionary views. The temperate and non-dogmatic way in which he discusses affinities between various groups and families of vertebrata is very far removed indeed from a denial of evolution which hardly any zoologist of to-day would venture to make, least of all Mr. Sedgwick, whose own original investigations have had so important a bearing upon the validity of the general theory. What he does say, and with some emphasis, in which we cordially agree, is that phylogenetic trees so confidently expected some years ago become harder and harder to frame as new facts are discovered. The very problem of problems, so far as the present volume is concerned—viz., the origin of vertebrates themselves—is so far from solution that hardly any two zoologists can agree as to fundamental structures upon which to build a reasonable hypothesis. It might fairly be said, though with some mixture of metaphor, that most phylogenetic trees are convenient ladders for their authors "to climb down."

---

[1] THE LANCET, April 8th (p. 909), 15th (p. 983), and 22nd (p. 1047), 1905.

It is highly instructive to observe the views taken by Mr. Sedgwick as to more special cases of affinity. For he is one of a rapidly decreasing group of zoologists who are not in any sense of the word specialists but whose investigations have dealt with many groups and with many general problems. A zoologist of this kind is likely to take a saner and more comprehensive view of a given question which to the specialist appears of greater importance than perspective allows. On a question of bird affinity, for instance, the last person whose opinion is worth consideration is an ornithologist. The position of hatteria in the zoological series offers a fair test of zoological sobriety. Professor Huxley, who was well acquainted with that reptile, regarded it as "a lizard and nothing but a lizard," to quote as accurately as we can from memory. Later research has seemed to many to remove it from that settled position and to put it among ancestral reptilian forms. But that later zoological research to which we refer here has been in the hands of "bone and skin men" who speak disrespectfully of viscera and cannot grasp the fact that a dried skeleton does not represent all that can be learnt of an animal's anatomy. Mr. Sedgwick, balancing fact with fact and eschewing preconceived notions save those derived from a study of anatomy, does not see in hatteria so basal a form as we are led to regard it by some—indeed, we fear many. Geology appears to him to disprove any suggestion that tortoises have emanated from a reptile like hatteria. It may well, we think, be urged that the existing knowledge of the anatomy of lizards is so much in need of increase that speculations upon hatteria are distinctly "previous."

Though Mr. Sedgwick is, on the whole, in accord with Professor Huxley as to hatteria, he is not by any means a follower of the master in the origin of mammals. Professor Huxley taught very distinctly that of existing animals amphibia bear the closest resemblance to mammals. But of later years the opinion has been gaining force that it is among reptiles that we are to look for the "pro-mammal." With this view Mr. Sedgwick associates himself and here, again, we are in thorough agreement with him. But in all these speculations what we want is, as Goethe said, "light, more light."

To write an account of all vertebrate animals is at the present day an extremely notable achievement. Nor is it likely that so comprehensive a work could appear without some trifling errors. But there are not many. The only one that we have noticed is the statement that the New Zealand apteryx possesses no oil gland, so constant an organ in birds. It happens to be furnished with a particularly large one. This, however, is a blemish which serves to accentuate the general symmetry of the work.

Malignant Disease of the Larynx (Carcinama and Sarcoma). By PHILIP R. W. DE SANTI, F.R.C.S. Eng., Surgeon to the Throat, Nose, and Ear Departments, Westminster Hospital (late Senior Assistant Surgeon, Westminster Hospital); Lecturer on Disease of the Throat, Nose, and Ear, Westminster Hospital, Medical School. London: Baillière, Tindall, and Cox. 1904. Pp. 107. Price 4*s.*

IN Mr. de Santi's book great stress is laid upon the distinction, first made by Krishaber in 1879, between malignant disease affecting the true vocal cords and their neighbourhood and malignant disease appearing in the epiglottis and aryepiglottic folds. When arising in the former situation (or intrinsic as Krishaber called it) the lymphatic glands are not affected until after some time has elapsed, while in the other variety (extrinsic) the lymphatic glands are early involved. The practice advocated in this work is based chiefly on this very important distinction. The author describes the various manifestations of the disease, their symptoms and complications and then discusses the principles of treatment. Mr. de Santi is strongly of opinion that thyrotomy is the safest and most satisfactory method of dealing with nearly all those forms of carcinoma of the larynx which are suitable for operative interference. The book is clearly and carefully written and it will give a good idea of the subject to those medical men who have not devoted much attention to malignant diseases of this organ. When a second edition is called for we hope that the author will see his way to provide some diagrams and illustrations which would serve to enhance the value of the work for the ordinary reader, and we would further suggest that the utility of such a work as this would be increased by bibliographical references to the opinions and cases quoted.

An Introduction to Physiology. By L. A. HODGKINSON LACK, M.B., Ch.B. Edin. Edinburgh and London: William Green and Sons. 1904. 8vo, pp. 210. Price 8*s.* net.

THIS volume is of the nature of a scheme or syllabus which will prove of service to those who are attending a course of physiological lectures and has the advantages and disadvantages of such a treatise. The advantages are that the more important facts of physiology are brought before the student in an orderly and compendious form with such additions as he may have jotted down in the laboratory or the class room on the blank pages with which the book is interleaved. The disadvantages are that it presents these facts in an interrupted and fragmentary form, leading him to suppose that he has mastered the whole subject, and, in addition, that, however the author may disclaim the intention of making his treatise subservient to cramming, it becomes inevitably used for that purpose by the indolent and inattentive. It no doubt saves much trouble to the student to learn the tables representing the differences between albumin and globulins, but the danger is that he simply acquires the facts by rote and omits to perform the experiments on which they are founded.

The following are a few of the notes which we have made in examining the work. The introductory chapter on Histology, giving the mode of preparing animal tissues for the microscope, is very satisfactory and useful. The modes here given of demonstrating Nissl granules and of iron in cells as well as the stages, 25 of which are given by the author, of staining cells with hæmatoxylin and eosin, are not often given so well in histological works. In the description of the structure of muscle some confusion is created by the statement that "in the middle of the light stripe is Hensen's line." It should be in the middle of the dark stripe. The results of section of a spinal nerve and its roots are rendered clear by an intelligible diagram. An explanation is required in the section on nerve of various terms, such as "diphasic" and "commutator." In describing the sounds of the heart Dr. Lack attributes the first sound very properly to the sudden tension of the auriculo-ventricular valves but remarks that the ventricular contraction may *possibly* aid in its production, a view that can hardly be sustained on the well-established evidence that it is still distinctly heard after excision of the heart and on the evidence obtained by Wintrich with his resonators. In the section on lymph the author states that the cause of the lymph flow is, amongst other factors, muscular contraction; it should, we think, have been added, aided by the numerous valves contained in the lymph vessels. The special senses are very briefly described and the reproductive system and development are more fully given. The work would be improved by the introduction of a few more experiments and also of an index.

The Surgery of the Head. By BAYARD HOLMES, B.S., M.D., Professor of Surgery in the University of Illinois; Professor of Clinical Surgery in the American Missionary College, Chicago; Attending Surgeon to the Chicago Baptist Hospital. London: Sidney Appleton. 1904. Pp. 569. Price 12*s.* net.

THIS is the first volume of a text-book of surgery and therefore we must consider it as a part of a larger work. The author tells us that it has been his endeavour to discuss at greatest length those conditions which are most frequently met with and the next share of attention is given to conditions rarer but requiring instant relief, and thus the reader is not given a false idea of the relative importance of the different subjects. Dr. Holmes does not tell us how many volumes he intends to write to complete his text-book of surgery but we may express the hope that the succeeding volumes will be as good as the one before us. The author writes in a pleasant, simple style and his explanations are clear. There are many statements which we might controvert but on the whole the teaching is that which is generally accepted. We are pleased to see that many illustrative cases have been inserted which assist greatly in enabling readers to understand the subject. Every case given demonstrates some definite point in the diagnosis or the treatment. The illustrations are useful, the coloured plates being especially good. The reader will find in this book that which he is most likely to need in actual practice and we consider, therefore, that the work is more likely to prove of use to the qualified practitioner than to the student working for an examination.

A Monograph of the Anopheles Mosquitoes of India. By S. P. JAMES, M.B. Lond., Captain I.M.S., and W. GLEN LISTON, M.D. Glasg., Captain I.M.S. With 15 coloured plates. Calcutta: Thacker, Spink, and Co. 1904. Pp. 132. Price 24*s.* net.

MONOGRAPHS and other kinds of books upon mosquitoes are not by any means rarities on the shelves of libraries and in the offices of journals in these days, the sudden and increasing output of such publications being, of course, due to the recent acquirement of knowledge upon the history and the causation of malaria. Indeed, this kind of literature has but one serious rival—memoirs upon the histological nature of cancer. But while the student of cancer contents himself with copious memoirs in scientific journals the historian of mosquitoes is rarely content with anything under an expensive and separately published monograph. It is to the most recent of this plenteous series that we now desire to direct briefly the attention of naturalists and medical men. The principal feature in this work is its limited, but within limits exhaustive, character. The way to accumulate this kind of knowledge is not, in our opinion, to be brought about by a confused and random collection of facts and notes from every quarter of the globe but by concentrating activity upon a limited section at a time. This is exactly what the authors have done. Their contribution to entomology is neatly rounded and polished. No doubt it is not actually exhaustive. Future hunting will discover more species of the anopheles in India. But such discoveries can be added on to the present work which, while representing current knowledge, is a platform from which an advantageous start may be made. The veriest novice in zoology could hardly fail to identify from the clear descriptions and from the elaborately coloured plates the mosquitoes of this genus which happened to fall in his way. The descriptions are very full and the plates represent a great enlargement from the actual size. An introductory plate, which represents the "skeleton" of the insect with names written clearly against every joint and every vein, renders it easy to comprehend the ensuing and coloured figures. It is to be hoped that the authors will continue their work and will extend their field of labour to other genera of mosquitoes and to other countries.

LIBRARY TABLE.

A Woman's Words to Women on the Care of their Health; and *The Mother's Guide to the Health and Care of her Children.* By MARY SCHARLIEB, M.D., M.S. Lond. London: George Routledge and Sons. 1905. Pp. (each) 164. Price of each 1*s.*—The first edition of the first of these volumes appeared in 1895; the book has been thoroughly revised and is now published at one-sixth of the cost of the first issue and as a companion volume to "The Mother's Guide to the Health and Care of her Children." Both the volumes are well and carefully compiled and will spread much useful knowledge especially concerning the laws of health and the normal functions of the body. Mrs. Scharlieb is evidently in favour of universal circumcision, for under the heading of paraphimosis she observes: "If all male babies were carefully circumcised this accident would not occur."

Contribution à l'Étude de l'Intoxication d'Origine Ophidienne. (A Contribution to the Study of Snake Poisoning.) By Dr. VITAL BRAZIL. Paris: A. Maloine. 1905. Pp. 26.—Dr. Vital Brazil, who is director of the Institut Sérothérapique of San Paulo in Brazil, states that almost all the poisonous snakes of Brazil belong to the family of crotalidæ and to the two genera lachesis and crotalus. Of the former genus there are several species but of the latter there is only one—namely, the crotalus horridus or rattlesnake. Dr. Brazil describes at some length the method of keeping snakes in captivity, the extraction of the venom, and the preparation of antitoxic serum by the inoculation of horses and mules. The antitoxic serum obtained by inoculation of lachesis venom is not antidotal to crotalus poisoning and *vice versâ.*

Dental Surgery for Medical Practitioners and Students of Medicine. By A. W. BARRETT. Fourth edition. London: H. K. Lewis. 1905. Pp. 159. Price 3*s.* 6*d.*—That this book should have reached a fourth edition seems sufficient proof of its utility to the busy medical practitioner. We rather hoped in a new edition for a clear account of the importance of oral sepsis in regard to disease and the necessity of impressing upon practitioners the danger of retaining in the mouth septic teeth. The author seems to lay too much stress upon the retention of temporary molars and his dictum that "temporary molars should never be extracted save as a last resource and where every attempt to relieve pain by other means has failed" is likely to lead to the retention of many teeth that would be far better away from the mouth. In another edition, too, we should like to see more explicit directions on the cleansing of the teeth and more remarks on the "Prevention of Caries."

The Horse: Its Care and Management. By HENRY E. FAWCUS. Edited by T. W. SANDERS, Editor of *The Profitable Farm and Garden.* Illustrated. London: W. H. and L. Collingridge. Pp. 127. Price 1*s.* 6*d.*—This little book is No. 9 in a series known as "The Profitable Farm and Garden Handbooks." Mr. Fawcus is a well-known authority on horses and the book is written to meet the requirements of people who own light and heavy draught horses. The author deals with the various breeds of horses and ponies, with the food question, with ways of feeding, with breeding and grooming, with the general care and management, and with the common ailments of horses. We are glad to see that Mr. Fawcus advocates that a supply of water should be always kept in a horse's stable. A chapter is devoted to the subject of stabling. The book is illustrated with drawings of the various breeds of horses. It is an attractive volume in which those who have the care of horses will find much practical and useful information. The final chapter is devoted to the donkey.

An Introduction to Pharmacognosy. By SMITH ELY JELLIFFE, M.D., Ph.D., Professor of Pharmacognosy and Instructor in Materia Medica and Therapeutics in Columbia University, New York. Fully illustrated. London, Philadelphia, and New York: W. B. Saunders and Co. 1904. Pp. 265. Price 10*s.* 6*d.* net.—This work has been prepared with the hope that it may meet the needs of students. Special emphasis has been laid on the microscopic rather than the macroscopic characters of drugs, although the latter are not neglected, and considerable attention has been given to the description of drugs in powdered form. In general features it resembles the book published in this country in 1903 by Mr. Greenish. The drugs studied in detail have been selected as those most typical of general drug characters. With the knowledge acquired from the types given the student should be equipped to pursue individual research of an economically practical nature. It is a book which will appeal to the druggist rather than to the student of medicine. The illustrations are excellent and the print and the paper of the book are all that can be desired.

Alcoholic Poisoning and Degeneration. By Professor G. BUNGE, M.D., Ph. D. London: A. Owen and Co. Pp. 27. Price 6*d.* net.—In this pamphlet Dr. Bunge advocates the total prohibition of alcoholic drinks. He lays particular emphasis on the aspect of the degenerating effects of alcohol and sums up the results of his statistical researches as follows: "As a rule, where the father has been a drinker, the daughter loses the power to suckle her children, and the capability is irrecoverably lost to all future generations. The incapability of nursing is no isolated phenomenon. It is accompanied by other symptoms of degeneration, in particular by a want of power to resist the inroads of disease of all kinds: nervous disorders, tuberculosis, decay of teeth. The children are insufficiently nourished, and so from generation to generation the work of deterioration goes on, leading at length, after endless suffering, to the ultimate decay of the race." He urges the most radical measures of reform. He writes that "no one can bring forward any scientific argument against the claims of abstinence and, in the long run, no power on earth will be able to withstand the demands of science; the whole history of the world teaches us this lesson."

The Book of the Potato. Illustrated. Edited by T. W. SANDERS, F.L.S., F.R.H.S., editor of *Amateur Gardening.* London: W. H. and L. Collingridge. 1905. Pp. 222. Price 2*s.* 6*d.* net.—All those who cultivate the potato will find this volume a useful guide on many points, and it is well worthy of careful perusal. The editor deals in turn with the history and the botany of the potato plant; with soils and their treatment; with manure and manuring; with how to propagate the tuber by seed, cuttings, eyes, and grafting; with how to treat the "sets" or "seed tubers" for planting; with the systems of planting; with how to force potatoes for early use and to grow them for exhibition; with lifting, storing, and marketing; with how to rear new sorts; and with the pests and diseases of the tuber. At the end of the volume there is a descriptive catalogue of 270 varieties. A feature of the book is an account of the practical operations necessary for planting and storing the tubers.

JOURNALS AND MAGAZINES.

The Practitioner.—A very interesting and speculative article upon Functional Insanity by Dr. Robert Jones is one of the best features in the May issue of this journal. Dr. H. Batty Shaw contributes a comprehensive and careful review of recent investigations on the physiology and the pathology of secretory tissues and Dr. J. M. H. Macleod in like manner treats of advances in dermatology. His article contains a valuable description of the x ray treatment of ringworm of the scalp with some convincing statistics from French authorities by whom the method has been more widely employed than has yet been the case in this country. Mr. Hugh M. Rigby writes on the Operative Treatment of Fracture of the Patella.

Journal of Comparative Pathology and Therapeutics.—The March number of this journal contains several important articles. The first of these on Dourine, by Captain F. S. W. Baldrey, of the Civil Veterinary Department, India, gives an excellent account of the conditions met with in a disease, to which so much attention has been given during the last three years. The author states that as the disease is conveyed solely by coitus it should not be a difficult matter to stamp it out, especially in India where all, or practically all, the entire horses are Government property. The editor, Professor J. McFadyean, contributes an interesting article on the Prophylaxis of Glanders and points out that the chief defects in the existing regulations with regard to glanders are (1) that they ignore the great service which mallein should render in diagnosis and (2) that they *do not* deal in a serious manner with the horses known *to* have been exposed to infection. Mr. Geoffrey H. Livesey supplies a Contribution to the Study of the Diseases of the Eye in the Dog, drawing special attention to a case of glaucoma. Dr. A. Edington, in an article on Biliary Fever in the Horse in Cape Colony, refers to the fact that as a rule one attack renders an animal insusceptible to further attacks of this disease. Part of Dr. Edward Nichols's paper on Implantation of Tissue and its Relation to Cancer is reprinted from the January number of the *Journal of Medical Research.* Other articles of interest are on Abnormal Genital Organs in the Domesticated Animals, by Professor James F. Craig, another on Some Points to be Considered in Connexion with Rhodesian Red-water, by Mr. Stewart Stockman, a series of clinical articles, and a number of abstracts, the most important of which are an article on the Diagnosis of Mammary Tuberculosis, a second on Immunisation against Tuberculosis by von Behring's Method, and a third on Piroplasma Bigeminum of the Immune Ox, by Dr. A. Theiler. Altogether this is a very interesting number.

Journal of Experimental Medicine. Vol. VI., Nos. 4, 5, and 6. Issued Feb. 4th, 1905. The Macmillan Company, Baltimore, Maryland.—At last we have received the completing numbers (4, 5, and 6) of Vol. VI. of the *Journal of Experimental Medicine.* It appeared as though this excellent journal had disappeared from our midst but we are glad to learn that it will continue to be issued under the auspices of the Rockefeller Institute for Medical Research and under the editorship of Dr. Simon Flexner and Dr. Eugene L. Opie. The papers, as we have come to expect in this journal, are excellent. The first of these, a Contribution to the Physiological Differentiation of Pneumococcus and Streptococcus and to Methods of Staining Capsules, by Dr. Philip Hanson Hiss, jun., is of importance because the author is able to show that the chief differential character usually depended upon for the distinction between pneumococci and streptococci—the capsule—cannot always be depended upon, as well-marked capsules undoubtedly occur in organisms which have been classified as streptococci whilst, as is well known, pneumococci in artificial cultures often lose this character. There are, however, certain metabolic activities which distinguish these two forms; for these we must refer the reader to the original paper. Dr. H. T. Marshall, Fellow of the Rockefeller Institute, contributes an account of some work done under Professor Ehrlich, "Studies in Hæmolysis with Special Reference to the Properties of the Blood and Body Fluids of Human Beings." One of the important points brought out is that the complement differs in amount in various specimens of human blood and that it is available for a variety of normal and specific amboceptors. A number of other observations almost equally interesting are here recorded. Dr. H. S. Steensland contributes a paper on Epithelioma Adamantinum; Dr. Martha Wollstein writes on the Bacteriology of Broncho- and Lobular Pneumonia in Infancy; Dr. Walter Ralph Steiner, M.A., on a case of Dermatomyositis, with Report of a Case which presented a Rare Muscle Anomaly but once described in Man (in this case the author found a degeneration commencing at the centre of the fibre and gradually passing to the periphery); and Dr. W. Ophüls describes Further Observations on a Pathogenic Mould formerly described as a Protozoon (Coccidioides Immitis, Coccidioides Pyogenes), a fungus of which up to the present only some six cases have been related. Dr. Martin H. Fischer contributes a paper on the Toxic Effects of Formaldehyde and Formalin, especially as to the action of this drug on the lungs, the stomach, the peritoneal cavity, the eye, the muscles, the liver, the kidneys, and other organs. The author points out that formalin is, directly or indirectly, chemiotactic for leucocytes. Dr. Norman MacLeod Harris describes a new bacillus, "bacillus mortiferus," which is pathogenic for man and animals. The high character of the work contained in this number makes us welcome the fact that we have had to do with a case of suspended animation merely and not with one of dissolution as far as this excellent journal is concerned.

Veterinary Journal.—The April number of this journal contains an original article by Mr. T. B. Goodall, F.R.C.V.S., F.L.S., on Blood-sucking Flies as Inoculating Agents and Disease Disseminators. Mr. Goodall is recognised as an authority, and his descriptions and sketches though short are interesting and give a very good idea of the part played by these small organisms in the dissemination of disease. Then follow several clinical articles, translations, and short extracts. The most important of these are abstracts from a report on Fowl Cholera issued by the Californian College of Agriculture and of papers on Internal Massage in the Horse in the Treatment of Tympanitis, on Dental Caries in the Horse, on Poisoning in the Pig from the Débris of Silk-worm Cultivation. Notes on Spavin, and the Abuse of Artificial Selection, the latter of which deals with points some of which are of great interest to readers, reviews, and correspondence, complete this number.

Journal of Pathology and Bacteriology. Vol. X., No. 3, April, 1905. London and Edinburgh: Young J. Pentland.—The April number of this journal is a very interesting one. Dr. V. E. Henderson of Toronto contributes an excellent paper on Joint Affections in Tabes Dorsalis, the result of work carried out in Professor Chiari's laboratory in the University of Prague. Dr. Henderson, after giving a *résumé* of recorded cases, presents a new series examined by himself and after describing the anatomical changes found comes to the conclusion that the most important pathological anatomical change is the degenerative lesion in the sensory nerves and paths and that the changes in the joints are the results of trauma, using the term to include not only injuries to the joints from external causes but also those resulting from undue strains and wrenches; further that this is largely owing to the prevailing analgesia, though this may be aided by vaso-motor or reflex trophic changes, which, again, may in turn be influenced by the prevailing sensory lesions. Dr. Henderson contributes a very large number of references and illustrates his paper with a number of reproductions of capital photographs. Another interesting paper is one by Miss C. B. Sheldon Amos on the Effect of Ligature of One Ureter. This work, which has been carried on in the Porte Vieux Laboratory, Alexandria, is of excellent quality and has considerable bearing on the question of secretion by the kidney, especially in its relation to toxic conditions. A paper entitled "An Unusual Duodenal Hernia," by Dr. Albert J. Chalmers, registrar to the Ceylon Medical College, is interesting as an account of a hernia into the recessus inter-mesocolicus transversus which took place, probably, some years before the death of the patient. There are two excellent papers on the blood in disease—one on the Blood Changes in Plague, by Captain Leonard Rogers, I.M.S.; and the other on the Leucocytosis of Typhus Fever, by Dr. Andrew Love, senior resident assistant physician to the Belvidere Fever Hospital, Glasgow. Both these papers indicate what a prominent part the examination of the blood has come to play in the study of disease. A very interesting and useful feature of this as of the last number is that a card catalogue index is supplied not only of the current number but of Vols. III.-VI. Cross references are given in this so that if the references are cut out, pasted on cards, and arranged in alphabetical order under "authors" and "subjects" any paper can be found within a couple of minutes; subjects can be grouped and dates readily obtained. The principle adopted is similar to that in use for the indexing of the Proceedings of the Royal Society of London and cannot but prove of very great value to those who wish to refer to papers that have appeared in this journal.

Journal of the Scottish Meteorological Society. London and Edinburgh: William Blackwood and Sons. 1905. Pp. 187. Price 12*s.* 6*d.*—In the current issue of this annual volume the first of the original articles is a paper on the Treatment of Climatological Observations which was read at a meeting of the Scottish Meteorological Society on Dec. 6th, 1904, by Mr. W. N. Shaw, secretary of the Meteorological Council. Mr. Shaw's object is to obtain a combination of the daily weather reports with the more elaborate observations recorded at the climatological stations and to classify climatological data according to a limited number of types to be agreed on. The directors of the Ben Nevis Observatories publish an account of their endeavours to obtain sufficient financial support for carrying on these observatories. The observatory on the summit of the mountain at an elevation of 4400 feet was opened in 1883 and it unfortunately had to be closed (together with the one on the low ground) at the beginning of October, 1904. The bulk of the volume is occupied by tables of systematic meteorological observations made at about 60 stations in Scotland for the years 1902 and 1903.

Birmingham Medical Review.—The March number of this review contains some very interesting articles. Mr. H. Gilbert Barling treats of renal mobility and unhesitatingly advises operation in severe cases which present troublesome symptoms. Mr. J. W. Taylor urges the value of colpotomy in cases of puerperal fever of medium severity with thrombosis of the pelvic veins. The vaginal roof is opened up on the side chiefly affected and search is made for small abscesses or pockets of pus in the uterine wall and in the broad ligament. The Richard-Middlemore Post-graduate Lecture by Mr. D. C. Lloyd Owen contains a very useful account of recent advances in ophthalmic treatment.

Dublin Journal of Medical Science (April).—Dr. Walter G. Smith gives an interesting account of the relations of the chemical elements and of recent speculations as to the nature of the ether. Dr. R. J. Kinkead discusses puerperal convulsions and lays stress upon the personal factor at work in individual cases in addition to the toxins present. Dr.

A. J. Smith narrates his experience of Bossi's dilator and decides that it is a valuable instrument in suitable cases but that it is dangerous when the cervix is long and not "taken up," especially in case of placenta prævia.

West London Medical Journal.—To the April number of this periodical Mr. J. D. Malcolm contributes a useful paper on Extra-uterine Fœtation. Dr. Alexander Morison discourses of boldness in the treatment of some phases of pneumonia, advocating recourse to blood-letting when there are signs of engorgement of the right side of the heart. Other suggestions contained in the paper relate to the use of an icebag applied to the head and to the employment of turpentine in case of profuse bronchial secretion. Mr. Cecil H. Leaf considers that the four antecedent events most constantly present in cases of cancer of the breast are errors of lactation, a family history of consumption, injury, and worry and anxiety.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) "WELLCOME" BRAND CHLOROFORM; AND (2) BOROFAX.

(MESSRS. BURROUGHS, WELLCOME & Co., SNOW HILL BUILDINGS, LONDON, E.C.)

(1) THE fact that chloroform used for anæsthetic purposes has been found to contain a definite though quite small amount of ethyl chloride was referred to in an annotation in THE LANCET of March 4th, 1905, p. 589, and apparently the presence of this volatile substance has a marked beneficial influence on the action of chloroform. It is stated by some authorities that chloroform quite free from ethyl chloride tends to produce cough and holding of the breath, and that this is not the case when the anæsthetic contains a trace of ethyl chloride. The "Wellcome" brand chloroform is prepared on the lines indicated and consists of perfectly pure chloroform containing a small but definite amount of ethyl chloride. (2) Borofax is described as an emollient possessing antiseptic and sedative properties. It is contained in collapsible tubes and consists of a cream-coloured ointment having a low melting-point. It is very agreeably scented and has a pleasant action upon the skin. The oily vehicle does not get rancid and, according to our experiments, is not saponified by aqueous caustic soda solution. It contains a mild and efficient antiseptic which renders it useful as an application for chaps, burns, scalds, and abrasions. In particular it is soothing to the skin which has been exposed to the sun or wind.

VINOLIA WHITE COAL TAR SOAP.

(VINOLIA CO., LIMITED, MALDEN-CRESCENT, LONDON, N.W.)

The presence of phenol compounds in this soap was confirmed by chemical tests. The soap showed a slightly alkaline reaction with phenolphthalein owing probably to the alkaline compound of coal tar acid which has been used. The soap basis is of excellent quality and quite free from crude compounds. The soap is an advance on many coal tar soaps in which crude and often inert oils are employed.

INFANTS' FOOD.

(T. FLETCHER AND SON, 98 AND 99, GREAT HAMPTON STREET, BIRMINGHAM.)

According to our analysis and examination this is a carbohydrate food modified by a special method of preparation. The analysis was as follows: carbohydrate, 75·21 per cent.; proteid, 11·02 per cent.; fat, 2·60 per cent.; sugar, 0·57 per cent.; mineral matter, 2·40 per cent.; and moisture, 8·20 per cent. The microscope showed unaltered starch cells. The food is very finely ground. The food used alone would not be suitable for infant use but employed as a supplement—that is, by its addition to good cow's milk—a very satisfactory food is obtained for those cases in which cow's milk alone proves indigestible. Presumably, this advantage is due to the mechanical action of the food on the curd. The directions given in regard to the preparation of this food are satisfactory.

CHINOSOL COMPRESSED TABLETS.

(THE CHINOSOL HYGIENIC COMPANY, 16, ROOD-LANE, LONDON, E.C.)

Chinosol, as is well known, has undoubted advantages as an antiseptic, deodorant, and disinfectant. It is non-corrosive, is relatively non-poisonous, and is readily soluble in water. In the form of tablets, each containing five grammes of the pure powder, chinosol is very convenient for use. In a comparatively small compass six tubes of 20 tablets provide an efficient antiseptic armamentarium. Antiseptic solutions of definite strengths for all purposes may thus be quickly prepared.

DIASTASE SETTERIE.

(THE BRITISH PHARMACAL CO., 12 AND 15, FURNIVAL-STREET, LONDON, E.C.)

According to our experiments this is a very active preparation of diastase, the amylolytic enzyme of malt. In its action upon carbohydrates it has the advantage of producing a partly digested mass which is free from acidity or objectionable flavour. We found that quite a minute quantity of the diastase rapidly liquefied a relatively large quantity of starch paste. The preparation is therefore well adapted for the predigestion of carbohydrate foods, while it may be used also for modifying cow's milk for the preparation of infants' food, since diastase appears to prevent the clotting of casein, at all events, in large curds.

VICHY WATER AND OTHER MINERAL WATERS.

(RETAILERS AERATED WATER AND SYPHON SUPPLY CO. ("RAWSCO"), 17 AND 18, LITTLE EDWARD-STREET, ALBANY-STREET, N.W.)

On analysis the Vichy water, which comes from "St. Yorre près Vichy," gave the following results: total mineral salts in solution, 7·46 grammes per litre, consisting chiefly of bicarbonate of soda, 6·93 grammes; and chloride of sodium, 0·53 gramme. On spectroscopic examination of the residue obtained on evaporation distinct evidence of the presence of lithium salts was obtained. The water is pleasantly sparkling but does not contain an excess of gas. It is free from organic impurities. The taste is pleasant and the water gives an agreeable cleansing sensation in the mouth. Vichy is, of course, well known as an excellent example of a natural alkaline water of repute in gastric catarrh, chronic indigestion, and catarrh of the urinary passages. A continued course of the water increases the alkalinity of the blood plasma. We have also examined samples of potash, soda, seltzer, and lithium water made by this firm. The purity of the waters leaves little to be desired and it is stated that they are prepared in silver-lined and electrically driven machines. The seltzer water contained 2·35 grammes of mineral salts and the alkalinity of the potash water was equivalent to 23·60 grains per pint of potassium bicarbonate, of the soda water to 12 grains per pint of sodium bicarbonate, and of the lithium water to eight grains per pint of lithium carbonate.

TOFFEE.

(JOHN MACKINTOSH, LIMITED, KINGSTON CONFECTIONERY WORKS, HALIFAX.)

After all, toffee, when made with honest materials, is one of the most wholesome of sweetmeats. It contains, of course, practically no proteid but a large proportion of carbohydrate in the shape of sugar and some fat in the shape of butter. We have examined specimens of "old-fashioned treacle toffee" and "cream toffee" respectively and we find that they are both of excellent quality and flavour and are evidently prepared from carefully chosen materials. The cream toffee yielded on analysis 2·39 per cent. of fat which proved to be butter fat. We could find no impurities or any evidence of metallic contamination,

CHELTENHAM NATURAL APERIENT WATER.

(THE CORPORATION OF CHELTENHAM, CHELTENHAM.)

Cheltenham possesses quite a number of interesting mineral springs which deserve greater attention at the hands of the medical profession than has hitherto been bestowed upon them. From the point of view of their chemical composition, at any rate, these waters should possess a therapeutic value not inferior to many continental waters of the same class. We have received a specimen of mineral water which is concentrated from the magnesic sulphated spring water obtained from the wells either in Pittville or Montpellier Gardens. The analysis shows that the water is rich in the purgative salts, magnesium and sodium sulphate. There are, besides small quantities of sodium chloride, bromide and iodide and traces of lithium chloride. The concentrated water, according to our analysis, has the following approximate composition: magnesium sulphate, 21·62; sodium sulphate, 14·10; sodium chloride, 9·06; and calcium sulphate, 1·08. These results are expressed in grammes per litre so that the total mineral salts amount to 45·86 grammes per litre. The water is indicated for use as an habitual laxative in chronic constipation or in portal congestion. It would be interesting to determine whether the mineral waters of Cheltenham show any radio-active property.

GOLD REEF CLOTTED CREAM.

(MESSRS. STONE AND SON, MONUMENT-BUILDINGS, LONDON, E.C.)

This is excellent cream sterilised and preserved in hermetically sealed tins. Our analysis gave the following results: fat, 31·35 per cent.; curd, 5·70 per cent.; mineral matter, 0·37 per cent.; and water, 62·58 per cent. Both the flavour and the consistence are satisfactory and no preservatives are used.

THREE STAR SWISS DRY MILK.

(THE SWISS DRY MILK CO., GLOCKENTHAL, SWITZERLAND; AND MESSRS. NETTLETON AND MORRIS, 17, HARP-LANE, LONDON, E.C.)

This "dry milk," it is stated, is prepared at Glockenthal in Switzerland, the milk being evaporated by the Just-Hatmaker process. It consists of a light dry powder which when dissolved in water gives a fluid having the appearance and the taste of ordinary milk. The flavour is particularly good, in spite of the process of manufacture which so often destroys the peculiar sweet flavour of raw milk. Our analysis of the powder gave the following results: moisture, 2·30 per cent; mineral matter, 7·30 per cent.; fat, 16·65 per cent.; milk sugar, 45·18 per cent.; and proteid, 28·57 per cent. Except as regards fat, of which there is a decided deficiency, this analysis corresponds with that of cow's milk from which the water has been removed by evaporation. The deficiency in fat should obviously prevent the preparation from being sold as whole milk, as if it were proceedings might be taken under the Sale of Food and Drugs Act.

RUSSIAN LOCAL GOVERNMENT CONTROL OF WORKMEN'S MEDICAL SERVICE.—A special committee sitting on the workmen's problem, presided over by the Minister of Finance, M. Kokovtzoff, proposes that the town and local authorities all over the country should, in place of the employers as is the case now, take over the medical assistance of the workmen, making the workmen contribute a certain premium. As it is they constitute over 80 per cent. of those who use the town hospitals. *It is calculated that to* cope with the question in St. Petersburg, where there are 160,000 workpeople, the council might get 600,000 roubles per annum to organise a workmen's medical service by making a levy of four roubles per person, part from the factories and part from the workmen themselves.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

(FROM OUR SPECIAL COMMISSIONERS.)

WEDNESDAY, MAY 10TH.

THE JOURNEY TO PARIS.—THE RECEPTION AT THE SORBONNE.

FROM the moment the British medical visitors set foot on French soil the series of welcomes, of speeches, and of felicitations began. At Calais, after a splendid passage, they were met by members of the reception committee and of the Calais committee of the French Alliance. At the Maritime Station the members of the Calais municipality, the Calais Chamber of Commerce, and the corporation of the Calais medical practitioners were waiting to receive the English visitors. A brief address of welcome was delivered by Professor F. LENNEL and Sir DYCE DUCKWORTH replied, saying:—

Messieurs,—Au moment où nous touchons le sol de votre belle France, je vous prie, au nom de mes confreres, d'agréer l'expression de notre profonde reconnaissance pour cet acceuil si gracieux. Ayez l'assurance, messieurs, que nous sommes vivement touchés de vos aimables efforts, et que nous, médecins anglais, désirons de tout notre cœur augmenter, autant qu'il est possible, une entente cordiale qui devrait toujours exister entre nos deux pays.

These words were greeted with enthusiasm and then a splendid bouquet of choice flowers was presented to Lady Duckworth. Flowers were also forthcoming for the other ladies present and these were ornamented with the combined French and British colours. At Boulogne, where a large number of British medical men disembarked, a similar welcome was awaiting them.

On arriving at Paris the Calais train drew up at a special platform, No 2, where the departures generally take place. Here Dr. Lucas-Championnière, vice-president of the organising and reception committee, Dr. Triboulet, the secretary, accompanied by Dr. Lombard, Dr. Marcel Briaud, Dr. Pierre Marie, Dr. Jarvis, Dr. Choppin, Dr. Chauffard, Dr. Debout-d'Estrées, Dr. Maegnat, Dr. Teissier, and many others, were waiting for their British colleagues. M. Sartiaux and M. Griolet, chief engineers of the French Northern Railway Company, Captain Churchward of the Chatham and South-Eastern Railway Company, and Dr. Perrier of the Railway Medical Service, together with M. Martin, the principal station-master of the line, were there also. The Northern Railway Company of France was not only thus represented by its leading officials but a waiting room had been set aside and elegantly decorated with velvet hangings and a brave display of French and English flags. On reaching this room Dr. LUCAS-CHAMPIONNIÈRE spoke a few words of welcome both [illegible] Sir DYCE DUCKWORTH replied [illegible] joy felt on reaching *la Ville* [illegible] the desire of the British medical profession to promote the *entente cordiale* between the two countries. The travellers were then conducted by members of the committee to carriages that had been retained for them and conveyed to the Grand Hotel, the Hotel du Palais d'Orsay, and other hotels. A similar welcome awaited those who came by the later Boulogne train.

In the evening between 9 and 10 the British visitors arrived at the magnificent new wing of the ancient Sorbonne. Here and by the care of M. Durand, secretary of the Academy, the first floor of the massive buildings giving on to the rue des Écoles was brilliantly illuminated. In the great saloon of the council of the Academy the leading members of the Paris University were waiting for the British medical men. On the landing and lobbies were tables where the visitors could obtain information and inscribe their names for inspecting the hospitals, assisting at operations, clinics, &c. Then a door was left open which led to the loggia of the grand amphitheatre—a model assembly hall. The new portion of the Sorbonne was commenced under the presidency [illegible] M. Carnot in time for the [illegible] he hall is one of the most [illegible] s in the world. Here the [illegible] ideal of M. Emile Trélat has been realised, the audience breathing pure, cold air that has not been warmed or tampered with, while the heat radiates from all the walls, ceilings, and floors. Then the seats are so admirably placed that they all command an equally good view of the platform. Finally, above the platform there is the magnificent fresco painting by Puvis de Chavannes. In other parts paintings give different episodes of the history of the University of Paris.

At about ten o'clock, most of the guests having arrived, seats were placed in a half circle in the great saloon and a request for silence was made. M. LIARD, Rector or President of the council of the University of Paris, was the first to speak. He said that he was pleased that to aid their endeavours to welcome their British visitors the May sun had at last made its appearance, adding its smiles to the salutations of the University of Paris. On the morrow of the day when Edward the Pacificator had given yet another pledge of friendship between England and France he was sure that these aspirations for peace would be echoed by the University of Paris. Indeed, far away in the dim past, even in the twelfth century, the University of Paris had been the means of bringing English and French together. In those days the students used to call themselves a nation. Thus there were at the University of Paris the nation of Picardy, the nation of Normandy, and the nation of England. In connexion with this last-named nation there still remained, and close by, the Rue des Anglais. The poor lodgings of this old and poor street, compared with the comfortable quarters of the Oxford and Cambridge students of to-day, would show what progress had been accomplished. But the ancient and rough accommodation was the forerunner of the university facilities now enjoyed. Each "nation" had its fête day at the University of Paris, that of the English being the day of the English king St. Edmund, which was loyally kept in both Church and tavern. On several occasions members of the "English nation" became rectors of the University of Paris, so that the British visitors had to-day come back to the cradle of their learning. After some more historical allusions M. LIARD described the wonderful scene enacted in the adjoining great amphitheatre some 15 years ago. All civilised nations had sent representatives to render homage to Pasteur on the occasion of his seventieth birthday. England had sent another man who, like Pasteur, belonged to all humanity. This was Lister. Here the British man of science described what he owed to the French man of science and then these two men to whom humanity owed an eternal debt of gratitude fell in each other's arms. A thrill vibrated through the vast audience, cheers and tears mingled as Pasteur and Lister embraced. These two men, so great in the services they had rendered, typified science striving to relieve suffering humanity. Then was cemented an *entente cordiale* that might become imperishable. It existed far above the plane where untutored elements might work mischief. The love of science, the love of preventing pain, was a force that flourished over and above the rivalries of parties and politics. It was not sealed with the fragile wax of chancelleries, but it grew out of a true sentiment and would be strengthened by such meetings as that which now honoured the University of Paris.

M. LYON-CAEN, general secretary of the society of "The Friends of the University," rose to apologise for the absence of M. Casimir-Perier who was too ill to attend.

Then Dr. BOUCHARD, President of the French organising committee, welcomed the visitors. He was especially pleased to meet them within the walls of the university, where from the very first learning found a haven from the surrounding savagery. The old, old buildings had been renovated by modern art and science but the university remained true to its glorious traditions. In the name of the wives of the French medical men he extended a special welcome to the ladies who had come from England and graced the Sorbonne by their presence.

This being the last of the speeches on the French side the band of the Fortieth Infantry, which was in the next room, played the "Marseillaise" and the audience rose and applauded in honour of the French National Anthem.

Sir WILLIAM BROADBENT replied in French on behalf of the British visitors. He remarked that this visit had become a matter of greater importance than was at first anticipated. They had been received, not only by professional colleagues, but by municipalities, by the institute which placed Chantilly at their disposal; indeed, by the whole intellectual aristocracy of France. In such circumstances it was permissible to consider their visit in conjunction with two other visits that had done so much to draw the nations together. He alluded to the visit of King Edward the Peacemaker to Paris and that of M. Loubet to London. Then by the side of this great example there were the reciprocal visits of the pacific workers of both countries. The *entente cordiale* had existed a long time. It could be established from a distance but how much better it was to draw close to each other, to know each other personally, and that was precisely what he and his colleagues desired in welcoming the members of the French medical faculty to London and to-day in visiting them in Paris. This friendship must be maintained and strengthened and if the United States of America could be induced to fall in also then the peace of the world would be assured. The magnificent reception now granted would never be forgotten. He regretted the absence of M. Casimir-Perier who was greatly respected in England. (While Sir William Broadbent was thus endeavouring, and with much success, to return thanks the electric light failed and the audience was plunged into profound darkness. Nevertheless, the speaker continued and the audience kept their seats. In a little while candelabra were brought in but they only gave a dull light and it must be confessed that the whisperings as to the possibility of getting a light prevented the hearing of the latter part of Sir William Broadbent's speech.)

Professor CLIFFORD ALLBUTT, who also spoke in French, followed on behalf of the Universities of England and especially of Cambridge. He described his medical education in Paris and his indebtedness to Trousseau and other great French teachers. He made historical allusions, going back to the Alexandrian school and the classics of Greece. He spoke of the work of Charcot and Pasteur in the evolution of modern medicine and also contrived to allude to Victor Hugo's dream of a United States of Europe. He thought that the French and the British nations were made to work together. Their flags had the three same colours, symbolical of liberty, equality, and fraternity; there was only a diversity in form. Let the two nations draw together. Henry IV. had said that Paris was worth a mass; was not London worth even a rough Channel crossing? The seeds of a new era had been sown and only required water and sunshine to grow; London would provide the rain and they asked Paris for the sunshine.

Dr. GEORGE OGILVIE, speaking in French, replied on behalf of the Scotch Universities, reminding the audience that there was a Collége des Écossais as well as a Rue d'Écosse in Paris and that there had always been the most intimate relations between the Scotch and the French for centuries.

At the conclusion of this speech the band played "God Save the King," which was likewise listened to standing and received with cheers.

The visitors then strolled about the magnificent edifice, contemplated the pictures (for now the electric light had been restored), and refreshed themselves at the buffet. It was a brilliant and most enjoyable evening in spite of the little accident to the supply of electricity.

THURSDAY, MAY 11TH.

RECEPTION AT THE FACULTY OF MEDICINE.

The first function on Thursday was a solemn reception at the Faculty of Medicine. This venerable institution was definitely constituted in the middle of the thirteenth century. At that time the University of Paris became a State supported school. It was legally established and divided into four faculties—the faculty of the arts (literature and science), the faculty of theology, the faculty of civil and canon law, and the faculty of medicine. At the head of each faculty there is a dean or *doyen* who is elected for two years by the professors. The members of the French reception committee have been wearing throughout, suspended by two ribbons (one the French and the other the English colours), a reproduction of the great silver seal first used in the thirteenth century by the Paris Faculty of Medicine. It still bears the inscription, which time and rough usage have only partially effaced, "*Sigillum magistrorum Facultatis Medicinæ Parisiensis.*" The members of the faculty have not only preserved their antique seal but they still wear the ancient robes and cap. These they donned in honour of their British visitors and standing in rows under the classic porticoes of the well-known building in the Rue de l'École de Médecine the members of the faculty contributed to the picturesque effect of the scene. Indeed, but for them and the brilliant toilettes of the numerous ladies present the gathering, however pleasant in itself, would have seemed gloomy in its outward appearance. The everyday modern male attire does not help to make a picture and tends not to enhance but rather to mar the effect of monumental buildings selected for solemn receptions. But on this occasion appearances were saved by the gallant display of gold braid and crimson silk which adorned the members of the Paris Faculty of Medicine, and also by the complimentary and in many instances the successful manner in which the English ladies strove to imitate the elegance in dress of their Parisian sisters.

After a while the crowd moved to the great amphitheatre and there the new Dean of the Faculty, Professor Debove, with Sir William Broadbent by his side, occupied the central position of the hemisphere. After the half circle of seats that rise up nearly to the ceiling had been occupied, Professor DEBOVE made a short speech. He was much applauded when he said: It is stated that science has no country but that men of science have a country. Nothing can be more exact. Our common country is a nation where people are not persecuted for their political or religious theories. There that disgrace to civilisation war, is unknown. The citizens of that country labour so that by the accumulation of knowledge they may force back and farther away the surrounding shades and darkness which still envelop us with poverty and misery, and cause diseases that are preventable and illness which we strive to cure. Being citizens of the same country we were not surprised by the hearty welcome that you gave us last year in London and to-day we are happy and proud to receive you in our ancient faculty. You are here in a building which belongs to us all and its very walls welcome you as friends whose visit was impatiently anticipated.

The Dean's remarks were so well appreciated by those who understood that he was prevailed upon to repeat them or a portion of them in English for the benefit of those who did not know French. Then Sir WILLIAM BROADBENT replied with a few words of thanks, after which guests and visitors proceeded to visit some parts of the building. They wound their way through the long room that constitutes the recently enlarged library, where in the course of a day there are sometimes as many as 500 students who come to consult the precious collection of books. The Orfila Museum with its many anatomical specimens was likewise visited. The council chamber of the professors of the faculty was selected as the place for leave taking, for the visit had to be brief there being two other functions the same afternoon. This room is fitted with chairs such as might be seen in a small parliament or municipal council. The walls are entirely concealed by sumptuous Gobelin tapestries of the seventeenth century. The colours are sombre and convey a sense of seriousness and dignity but there was not much time to examine and to admire as it was necessary to proceed to the Hotel de Ville.

RECEPTION AT THE HOTEL DE VILLE

Everyone acquainted with Paris life and French politics knows the importance of a reception by the great governing body of the capital. In vain the Central Government rank the President of the Paris Municipal Council with the Prefect of the Seine and the Prefect of Police, it is the voice of the elected representative of the people, and not the functionaries of the Government which carries the greatest weight in
the aspirations of the
instance the Presidency
most appropriately by
contributed to bring about many sanitary improvements. Dr Paul Brousse is well known to sanitary reformers. He is also well known politically as having always and even when the idea was far from popular, striven to bring about the nearest possible approach to an alliance between England and France. In these circumstances he lent himself with more than usual energy to the task of emphasising the significance of the visit paid by the British medical men. For such purposes the people of Paris have known how to build for themselves a palace that would do honour to any court in Europe. Those who had never visited "the town's mansion or hotel" (Hôtel de Ville) were lost in wonder and admiration. More than one of the London visitors was heard to murmur that the London county councillors must see the Hôtel de Ville. This admiration continued and was emphasised as after the ceremony of reception the guests wandered through all the ballrooms and other apartments. This was the more interesting as a plan was provided with a list of the pictures and the works of art.

At first the guests gathered in the saloon dedicated to literature but soon the ladies were directed to the central saloon which occupies the middle place in the three rooms devoted to literature, art, and science. Under Bonnat's magnificent ceiling representing the Triumph of Art, the ladies were invited to sit in a half circle. Facing them, and forming another half circle, was the Paris municipal council. The gentlemen stood on both sides and the finest military band of France that of the Republican Guards was in the third room. In this manner any unsightly crowding together was prevented and the eye could travel from group to group, each having its significance and interest. The opening between the rooms is so wide that it was easy to see from one to the other.

Dr PAUL BROUSSE as President of the Municipal Council was the first to speak. After thanking the French organising committee for bringing their English visitors to the Hôtel de Ville, he alluded to Sir William Broadbent's remark that the scientific *entente* had very effectively preceded the political *entente*. Dr Brousse urged that medical men were well suited to be the diplomates of peace. On the battle field and in the consulting room the medical man only saw friends whom suffering had raised to the dignity of patients and victims. He continued: 'Each man of science, without doubt has a country of his own. But when animated by his love of scientific research he soon rises to such heights that under him the most natural of frontiers are effaced, the mountains are flattened down and the widest channel seems but as a silver thread. On the high summits of learning if, according to Victor Hugo who was our poet and your guest names such as those of Darwin, Lamarck, Jenner, Pasteur, Lister are mentioned no one whether pupil or master thinks of the diversity of the countries whence they came. These benefactors of humanity, among whom you have already taken your place gentlemen appear as if they were compatriots as if they were the sons of a new city an ideal city possessed of some truly superior essence. Nothing could be more natural than that *l'entente* should number you among its precursors. You would not forgive me, gentlemen, if when dealing with this matter I did not render homage to your sovereign, King Edward VII, whose very politic intervention at so perilous a moment assured us that supreme blessing peace. Nevertheless as in regard to all great historical events this friendship was not the fortuitous product of one mind or will. We had to reckon with the time necessary for all natural evolutions and it is precisely this laborious genesis which proves its necessity and offers the best guarantee for its solidity and durability. In this respect allow me to communicate a souvenir where my personal vanity may find expression. If I have to-day the great honour of saluting in these saloons the illustrious representatives of British science I had also the joy 23 years ago of welcoming to Paris in the name of the workers of France the delegates of your trade unions, some of whom were Members of your House of Commons and who came over here to conspire with us in favour of the Channel Tunnel. We worked together with admirable ardour to bring our two peoples nearer to one another. We wanted to facilitate the exchange of ideas and of products. Our solicitude even took into consideration the delicate constitution of certain stomachs. We were not successful, we did not by piercing the tunnel prevent sea sickness, so we must look to you, gentlemen, for a more effective treatment of this malady. But we were none the less the workers and precursors of *l'entente cordiale*. I should commit an impertinence gentlemen, if as a modest medical practitioner I attempted to address to each of you the homage you deserve. This duty befits better my masters in the profession and with greater authority than I possess they will know how to accomplish this pleasant task. I remain in my place in thanking you for your visit in the name of the Municipal Council of Paris, in the name of the population of Paris who elected my colleagues and myself. I entertain the hope that our welcome will appear to you worthy of the occasion, particularly if you will be so good as to judge us by the loyalty and sincerity of our sentiments. Ladies we are most grateful to you for your gracious presence for the delicate charm it brings to this reception, rendering its souvenir ineffaceable. Once more, ladies and gentlemen, we thank you for your cordial visit.'

The Prefect of the Seine, M. DE SELVES, was the next to speak, and he alluded to the reception of the French medical men in London, to their admiration of the English hospitals. They had noted how much was due in England to individual initiative and how efforts were made to convert hospital wards into homes for the patients, where the charm of flowers and of pictures abounded. Perhaps France suffered from excessive centralisation and uniformity. He felt certain that both nations had much to learn from each other. The French, he added, would never forget that in 1874, "when our immortal Pasteur was isolated and medical circles did not seem inclined to recognise him it was among you and in the person of Sir Joseph Lister that he found his first ally. How great, also, is our joy when we recall the emotion felt at the memorable meeting held at the Sorbonne on Dec. 27th, 1892, when Lister, after having retraced the struggles of the past, approached Pasteur, and these two learned men embraced fraternally, thus, as it were, sealing in advance by the kiss of science the friendship of our two countries." The people of Paris were never indifferent to that which bore a high moral meaning. After some graceful allusions to the works on diseases of the nerves by the President of the British visitors, Sir William Broadbent, M. de Selves recalled that in 1904 at the London banquet a telegram was received from His Majesty Edward VII. which expressed the hope that the visit of the French medical men would be of benefit to both countries. The speaker concluded by inviting all present to join him in expressing with respectful diffidence their gratitude to His Majesty the King of England for having come to Paris, for having so powerfully helped to bring the two nations together, and their best wishes for the noble nation which the guests present to-day helped by their work to render great and honoured.

It was now the turn of the Prefect of Police, M. LEPINE, to speak. He dwelt on the fact that diplomatists might prepare and even sign alliances, but such agreements were only successful when supported by the popular sentiment and sanctioned by the intellectual *élite* of the countries concerned. He thought that this, the truest form of alliance, was being brought about by a solemn gathering together under the protecting wing of science. He alluded also to the fact that medical men were not merely learned but essentially practical; indeed, they were practitioners. The olive branch carried in their hand would therefore be an effective remedy against war.

The French speeches in honour of the British guests being now terminated the band played "God save the King" with great power, introducing new harmonies that were most effective. It was then the turn of the British to reply. It would seem, however, as if they had not been aware of the importance of the occasion. Many individual French medical men have made most generous and lavish efforts to entertain their British visitors. But, and apart from private initiative, the principal host is the Paris taxpayer; to him all the hospitals belong and all the public institutions where the British delegates have been so well received, and his representative is the Paris Municipal Council. In such circumstances some effort might have been made to prepare a suitable reply to the three important and eloquent addresses which were delivered at the Hôtel de Ville. Sir WILLIAM BROADBENT and Sir DYCE DUCKWORTH did certainly plunge into the breach and attempted to make up for the deficiency. But Sir WILLIAM BROADBENT himself said that it was impossible to reply worthily. He declared that he could not find words to say all that he would like to say and all that ought to be said. In London they had done their best but they had now been beaten. The French spoke gratefully and gracefully of their visit to London but this was eclipsed now. All that he could do was to thank them. The British would never forget the reception that they had enjoyed and the warm welcome that they had received from the town of Paris and from the French medical profession.

The band followed up the speeches of the British visitors with the "Marseillaise," then refreshments were handed round, a choir sang some old French popular songs, and the military band played various selections. The concert terminated by the Coronation March of H.M. Edward VII. by Saint-Saëns. This delicate compliment, admirably rendered by the band of the Republican Guard, concluded this most brilliant reception.

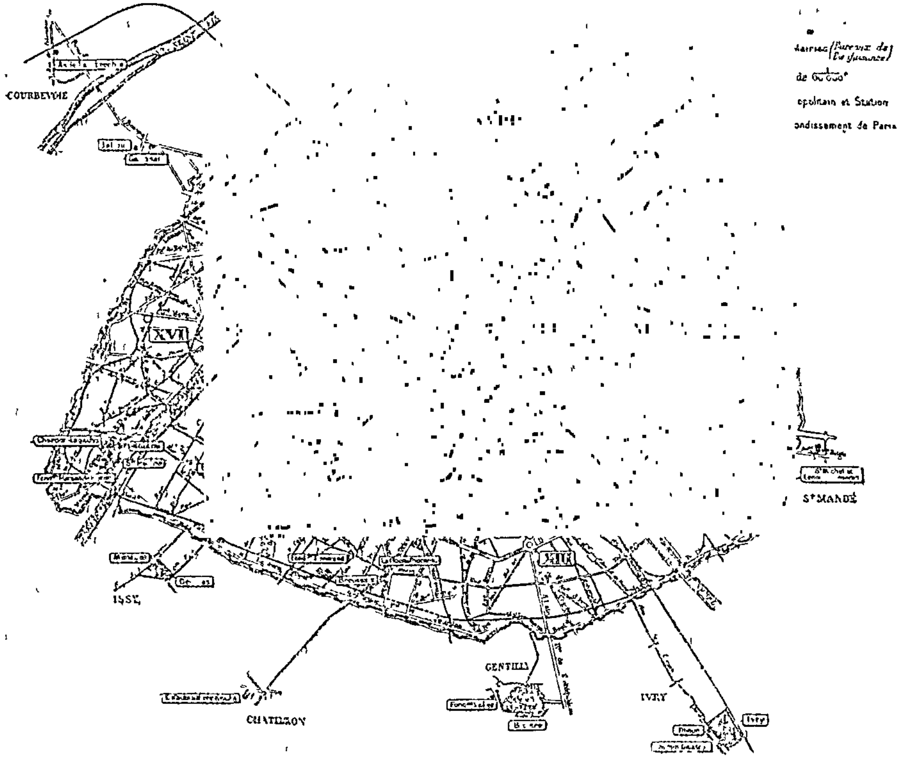
VISIT TO L'ASSISTANCE PUBLIQUE.

On Thursday afternoon, after the magnificent reception at the Hôtel de Ville, a considerable number of the visitors adjourned to the adjacent head offices of the Assistance Publique, in the Avenue Victoria, to be present at the somewhat formal reception, presided over by M. Mesureur, director of this important administration. The change from the luxurious surroundings of the Hôtel de Ville was very marked; no more marble staircases, no imposing statuary, no wealth of Gobelin tapestries and pictures; simplicity bordering on penury prevailed. We may remind our readers that the Assistance Publique of Paris emulates the functions of the Poor-law guardians, the Metropolitan Asylums Board, and the hospital administrations of London all rolled into one. It is subdivided into departments to deal with the multifarious branches of public assistance and is controlled by a director, nominated by the Prefact of the Seine and appointed by the Minister of the Interior. This official supervises the working of the huge "machine," but when any change is suggested which necessitates the expenditure of money not already provided for he has to consult the Conseil de Serveillance, a composite body made up of highly placed municipal and State officials, with whose approval only can such schemes be carried into effect.

The hospitals in Paris are municipal institutions to which all citizens have a *right* of admission in the event of their requiring medical or surgical assistance, differing in this respect from the London hospitals, where sundry restrictions are imposed and more or less enforced on candidates for admission. At the same time patients who are able to pay for their maintenance are invited to do so. From this point of view the Paris hospitals are administratively more akin to our Poor-law infirmaries, except that admission entails no social disqualification. The members of the senior medical staff are selected by competitive examination and are paid salaries amounting in the case of full physicians and surgeons to about £60 a year, the resident (junior) staff (*internes*) being allowed a small salary, about sufficient to cover their contribution to the hospital "mess." The latter hold office for four years, one year in each department of practice. They are drawn from senior students who have passed all their examinations for the doctorate but, not having presented their theses, are technically unqualified. Another important department is that which provides for the maintenance of abandoned children, of whom some 55,000 are brought up by the Assistance Publique. These children are all boarded out in the country, far from Paris, the more promising ones receiving in due course technical instruction in gardening, printing, housekeeping, and cabinet work.

The clerical staff numbers 900, while the hospitals and asylums give employment to 6000 attendants and 1500 workmen. The principle of extreme centralisation, as applied in the Assistance Publique, is claimed to result in great economy of administration and although the system presents some serious drawbacks there can be no doubt that the Administration is enabled to purchase supplies on vastly better conditions than would otherwise be the case. The expulsion of the Sisters of Mercy who had previously discharged the duties of hospital nurses threw a very heavy responsibility on the Administration and it is only during the last 10 or 15 years that the nursing-staff has been placed on an approximately satisfactory footing. The nurses are trained at the Écoles Municipales. They are drawn from the working classes and it is claimed that the fact of their belonging to the same social class as the majority of the patients enables them to sympathise more fully with the latter than the "lady-like" English nurse. It is, however, realised that the English system has advantages of its own which it is hoped to obtain by the institution of an Ecole d'Infirmières at the Salpêtrière Hospital. The new nurses take the place of the men (*infirmiers*) who formerly did much of the ward work, to the unquestionable benefit of the patients for the now abolished *infirmier* was usually a man of rough exterior and coarse manners, ill-suited to have charge of the suffering poor.

The resources of the Assistance Publique, in addition to endowments, comprise a subsidy of 28,000,000 francs (£1,120,000) paid by the municipality, plus about £140,000 derived from a heavy tax on the gross receipts of places of amusement, fees paid by patients and gifts, making a gross aggregate of 47,400,000 francs (£1,896,000) per annum—by no means a large sum when one bears in mind the wide scope of the board's sphere of action. The expenses are given at 57,000,000 francs but we



Map illustrating the administrative stations of the Assistance Publique (Reproduced by the kind permission of the Director of the Assistance Publique, M. G Mesureur)

are not told whence the balance of expenditure over income is derived. Returning to the reception, which only lasted about half an hour, the Director, M. MESUREUR, welcomed the visitors and invited them to take cognisance of the details of the administration, the history whereof he briefly sketched. He was followed by M. FELIX VOISIN, Vice-President of the consultative committee, who explained the position of his committee with regard to administration and the mode of recruitment.

Short speeches in French were made by Sir JOHN W MOORE of Dublin and by Sir WILLIAM BROADBENT acknowledging the very great courtesy and kindness shown to the visitors at the reception.

THE CHILDREN'S HOSPITALS.

[illegible] ty of position in the [illegible] London, for in both [illegible] parts of the town and in the midst of the poorest populations. The Hospital for Sick Children in the Rue de Sèvres, better known as the Hôpital de l'Enfant Jésus, was erected as an orphanage by the Curé of Saint Sulpice at the cost of Marie Leczinska and the Marquise de Lussan in 1732. The foundation was altered during the Revolution and since 1802 it has been used for the purposes of a modern hospital. The buildings co [illegible] space and the hospital maintains no less than [illegible]. The wards, as might be expected, are not of [illegible] type and to modern ideas overcrowded. Thanks, however, to the minute care taken by the *personnel* the cases do well and the temperature appeared to be thoroughly satisfactory throughout the wards. Dr. Broca operated on a case of congenital dislocation of the hip, using a modification of the Lorenz method, which his radiographs show to be of a satisfactory character, for several of the cases have been under observation for many months and the head of the femur has remained in its new position He is careful, he says, only to operate upon one side at a time and he keeps the patients in bed for a much longer time than is the custom in England.

The Hôpital Bretonneau for Children was built in 1901 and is situated at Montmartre, almost as far away as is possible in Paris from the Hôpital des Enfants Malades. It contains 261 beds, to which at times of emergency 134 beds can be added There is also a large out-patient department Boys and girls are admitted up to the age of 15 years, but some limit is placed when it is possible to do so upon the number of children under the age of three years who are in the hospital at one time. The hospital is well built and upon [illegible] a separate pavilion for [illegible] to the highest standard of hospital [illegible] not overcrowded. Dr. Felizet performed an operation for excision of the knee in a case of tuberculous disease by a novel method which appears to give excellent results and he says that he has done more than 300 in the same manner. It consists essentially in the removal of all the epiphyseal tissues except the circumferential cartilage and subsequent disinfection.

In both hospitals it appears that there are many more [illegible] in children than is common [illegible] apparent as a result of the [illegible] geons that appendicitis is even more erratic in its course in children than in adults. Neither the pulse nor the temperature is a sufficient guide to the condition of a child with an inflamed appendix and all such cases require the most careful and constant supervision to avoid disaster. The Assistance Publique has several convalescent homes for children—namely, at Berck-sur-Mer (Pas-de-Calais), for the treatment of hip disease and other tuberculous affections of bone; at Hendaye in the Basses-Pyrénées for strumous children and for general convalescence at Forges les Bains; and at La Roche Guyon on the Seine, near Mantes. The French surgeons appear to put their operating theatres to a much more extended use than is the custom in England. With us they are devoted to operations alone; in France they are used for such patients as it may be necessary to anæsthetise and on occasion for the demonstration of clinical cases. The technique of the operation does not vary materially from our own; chloroform with or without oxygen and given by means of an apparatus seems to be the favourite anæsthetic.

Hôpital Boucicaut.

Attracted by the remark that the Boucicaut Hospital is the newest and at the same time the most up-to-date in Paris several of the visitors presented themselves at its portals at 9.30 on Thursday morning where they were very politely received by the director (M. Longepierre) and the senior members of the staff, Dr. Letulle (medicine), Dr. Chaput (surgery), Dr. Doléris (gynæcology), and others. Where there is so much to describe it is difficult to know where to begin. However, the pleasure of the visit was greatly enhanced by the magnificent weather which enabled the buildings and gardens to be seen at their best. Amongst the visitors were Sir W. Broadbent, Sir Dyce Duckworth, Mr. C. A. Ballance, Dr. Tyson, Dr. Dawson Williams, and several others. A word must be said of the origin of the hospital. Mme. Boucicaut, the late proprietress of the Bon Marché, on her decease left 10,000,000 francs to the Assistance Publique for the purpose of founding a modern hospital to be called after her, two of the wards being reserved for the reception of any sick members of the staff of the Bon Marché. The hospital was inaugurated on Dec. 1st, 1897, by M. Felix Faure, the then President of the Republic. It is built in the outskirts of Paris on an area of about 30,000 square metres, of which one-fourth is occupied by the buildings, the remainder comprising the gardens and courtyards. The official number of beds is 194, although more are in use. All the arrangements suggest the most careful forethought. The hospital is built on the small pavilion system, the surgical wards being subdivided for the reception of septic and aseptic cases respectively, the cases being first investigated in a separate reception room before admission. On the medical side the tuberculous cases are isolated. On arrival the patients are washed and provided with sterilised clothes (blue cloth and canvas shoes); their own clothes are then disinfected and returned to them on their departure. If the diagnosis is clear the patients are then removed to the wards; in doubtful cases they are kept in an observation ward for as long as may be necessary. There are the usual waiting-rooms and surgical, medical, and gynæcological rooms. In the waiting-room there is a striking picture representing the dwelling of a poor family, the father on his death-bed surrounded by his wife and children. The picture is entitled "Death from Alcoholism." In the out-patient department there is a special theatre with adjoining sterilising room for small operations not necessitating admission into the wards. The eye is immediately arrested by the presence of spittoons suspended on the walls at rather frequent intervals. These occur chiefly in the out-patient department, the intention, no doubt, being to lessen risk from the habits of new and ill-disciplined arrivals. The wards are strikingly roomy and airy, dome-shaped and tiled, with rounded corners, so that thorough cleaning may be obtained by means of a hose. Dr. Letulle has a horror of brooms and feather brushes (plumeau) and has devised a cartoon representing a skeleton (the symbol of death) carrying brooms on the shoulder and brushes about the waist, fleeing from a jet of water which has been turned on it by one of the porters. Beneath the drawing is the following inscription: "Mort a balai! Mort au plumeau!! De l'Eau! Encore de l'Eau!! Toujours de l'Eau!!! Jamais trop d'Eau!!!!" Judging by the beautifully clean aspect of the place it is easy to imagine that water for cleansing purposes is not stinted. The beds appear to be rather close together but no doubt the proper amount of fresh air per patient is duly obtained, as the wards are lofty and wide and many windows are provided. A goodly supply of large-sized thermometers is kept in carbolic solution in each ward. The temperature is always taken in the rectum, never in the mouth. There is also an obstetric and gynæcological section under the care of Dr. Doléris, the arrangement of the wards being similar to that of the surgical and medical ones—that is to say, the greatest care is taken to separate septic from aseptic cases. In the obstetric ward were a few women awaiting their confinement, when they are removed to the "labour ward." Another ward is set apart for the newly born children—cots on one side and incubators on the other. This ward is provided with wet nurses who are no doubt carefully selected. The whole of the gynæcological section is rigorously separated from the others and there is no intercommunication. The laboratories all give the impression of being in a very workmanlike state of efficiency, the one devoted to radiography appearing particularly complete. The arrangements connected with the mortuary and post-mortem rooms apparently leave nothing to be desired. One of the striking features of the institution, and to which Dr. Doléris called special attention, is the endeavour to enhance the value of the so-called isolation of the various pavilions by the construction of underground passages provided with a network of rails by means of which supplies of all sorts are sent on trolleys to the various wards. In these passages are seen hot-water pipes, electric cables (for transmission of power to work the lifts and to supply the illumination of the pavilions), and other objects connected with the interior economy of the place. The kitchen is roomy and admirably served. One of the conditions of the bequest was that the religious element should not be abolished; hence the small chapel and the Augustine Sisters. The latter are only to be seen in three hospitals in Paris—viz., Hôtel Dieu, St. Louis, and Boucicaut, the headquarters of the order being at the Hôtel Dieu. The visitors were provided with refreshment, consisting of excellent champagne and cakes, &c., the former having been carefully selected of the "extra dry" quality to suit the English palate. Short speeches were delivered (in English) by Dr. Doléris and (in French) by Sir William Broadbent. The entire group was photographed, after which Sir William Broadbent called for three cheers for the staff of the hospital. The greatest cordiality prevailed and it may be said that the visitors were genuinely gratified at the extraordinary pains which had been taken to render their visit instructive and interesting.

Friday, May 12th.

The Hôtel Dieu.

As the most ancient and probably the most important of the Paris hospitals the Hôtel Dieu attracted a considerable number of visitors. The present building, which covers 21,770 square metres, was built, or rather commenced, in 1865, and there are many practitioners of the present generation who can recall the musty, more or less dilapidated hospital which spanned the small arm of the Seine on the opposite side of the square near the Cathedral. The old building dated back to the seventh century and only two portions of it remain. Completed in 1877 the present Hôtel Dieu nominally contains 828 beds, though the number has been added to regardless of space when there is extra pressure on the accommodation. It is an imposing structure, quadrangular in form, and spaces of no less than 11,389 square metres are laid out in courtyards and gardens. The staff includes names—Dieulafoy, Le Dentu, Lucas-Championnière, Champetier de Ribes, and others—that are well known throughout the world.

The visitors were received by the staff and told off into parties according to the departments in which they were most interested. It would be impossible to exaggerate the courtesy and kindness with which they were greeted and their wishes acceded to. The nursing question was naturally one to which special attention was given. The problem that presented itself in the substitution of lay nurses for sisters of mercy, though not yet completely solved, is in a fair way to attain success. The staff spoke very highly of the services rendered by the *infirmières* trained by the Assistance Publique, though admittedly they are drawn from a different social class to that from which English nurses are obtained. The beds, it is true, are closer together than is consistent with English taste but, thanks to the colossal budget at the disposal of the authorities, no expense is spared in keeping this and other Paris hospitals thoroughly abreast of the times. The operating theatres—which somehow always come in for special attention—are palatial and it would be difficult to suggest any direction in which, in the light of our present knowledge, improvement would be possible.

HÔPITAL NECKER.

He who would be well informed in all matters concerning the cardio-vascular system makes a point of spending a portion of his time at the Hôpital Necker. As hospitals go in Paris, it is not a very large one. It has about 500 beds, a proportion of which is set apart for chronics and incurables. It has been called by various names, such as La Charité, Hospice de Saint-Suplice, Hospice du Gros-Caillou, and Hospice de l'Ouest, but it is now known by the name of the lady, the wife of the famous banker whom Louis XVI. called in to arrange the national finances, who was mainly instrumental in founding it in 1776. To the Hôpital Necker is attached M. Huchard, an authority of European reputation on all matters cardio-vascular. He used to be at the Hôpital Bichat and was still there in the early "nineties" when he published his classical work on "Diseases of the Heart." His pride in his present post knows no bounds, for it was at this hospital that the famous Laennec did all his best work, and of Laennec M. Huchard speaks with an admiration and a veneration amounting almost to adoration. He is the fortunate possessor of one of the "master's" stethoscopes, which he handles—and when he gives it to you, begs you to handle—with becoming reverence. It is a commonplace enough looking implement; a straight tube of wood with a hole which is small considering the inordinate thickness of the wood, and no ear-piece. But it belonged to the master and M. Huchard guards his relic with all the jealousy of the enthusiast.

To the question, "Is this a hospital special to the diseases of the heart?" came a most emphatic negative. M. Huchard is a great teacher, but he is not in any sense of the term a specialist. His teaching is appreciated not only because he is clear and is possessed, conspicuously possessed, even among the French, of the inestimable gift of striking and even dramatic expression, but he is a strong man—strong enough, that is, to admit his errors and to use them as texts whereon to hang lessons for his pupils. In his class-room is a letter-box into which any student may at any time, anonymously or otherwise, place a piece of paper begging him to explain over again some matter which did not appear sufficiently clear and into which may be put a round robin signed by not less than ten requesting him to deal at his next lecture with a particular subject. M. Huchard's paternal attitude towards his pupils is further evidenced by the fact that his lecture-room was reconstructed mainly at his own expense and it is characteristic that he should have dedicated it, under the name of Amphithéâtre Laennec, to the memory of his great predecessor. And yet, in spite of the treasured stethoscope, which is produced only on state occasions, and in spite of other evidences of homage to his greatness, the auscultatory methods of the master are no more respected here than they seem to be elsewhere in Paris. The ear is applied to the chest in the vast majority of the cases and the stethoscope is used but seldom. This may have its advantages, especially in listening to the back and in men, but in the case of a woman with what they call in Paris an opulent bust the practice has disadvantages, both practical and sentimental, which are not to be gainsaid.

The beds at Necker are less crowded than they are at other hospitals and the wards are wider, but the same sense of scrupulous cleanliness pervades the place and the same admirable system obtains of washable overalls for those whose work brings them into immediate contact with the patients. The water-closets and lavatories, which are well separated from the wards, seemed to leave something to be desired. They are not as modern in construction as they might be and the faint ammoniacal odour suggested that they were not working properly. The female student is much in evidence at Necker. She is, indeed, everywhere and though at home we have become absolutely reconciled to her presence she still seems out of place in Paris. This is probably due to the views concerning what is suitable for a *jeune fille* which are known to obtain all over France and which differ considerably from those held on this side of the channel.

The number of English medical "*suivant le service*" of Professor Huchard was very considerable, and upon several occasions he gave a demonstration of the manner in which he conducted his work at the hospital. He explained that an exhibition of cases was, according to his view, hardly desired by his English *confrères* and he preferred to try to interest them by the exhibition of new instruments and methods of treatment, &c. Among the former he showed a water spirometer so constructed that the quantity of water displaced (and therefore air expired) could be read off on a graduated scale. He used it for the comparison of results before and after certain forms of treatment. Several of the visitors were asked to test their expiratory capacity; none came up to the professor's requirements until one physician at last made a record. Everyone laughed and Professsor Huchard, approaching this gentleman, said: "Mais, mon cher, à la fin il faudra vous tuer! vous ne mourrez jamais!" After this a sphygmomanometer was exhibited which, it appears, is in constant use. The visitors were then shown some curves representing the extraordinary increase in strength shown by Professor Huchard himself as a result of the ingestion of sodium formate (in suitable doses). These charts are certainly very remarkable and a full account of this method of treatment may be found in Professor Huchard's brochure entitled "Action Toni-musculaire et diurétique de l'acide formie et des formiates." Passing from the wards to another part of the hospital Professor Huchard showed the visitors the lecture room (clinical theatre) and out-patient department which he had had built at his own expense He gave an account of his method of practical instruction and explained that he encouraged the students, in the way already described, to ask for further elucidation of some subject not thoroughly understood. He then pointed to the bust of Laennec (for whose memory he professes the greatest veneration) and remarked that he had named the lecture room after him—Amphithéâtre Laennec. To each party of visitors he triumphantly produced the stethoscope which had belonged to the great physician. The visitors shortly after took leave of the genial professor, carrying away with them a very pleasant recollection of his charming personality.

THE SALPÊTRIÈRE.

Who has not heard of the Salpêtrière? Further, it might be asked, what need is there of a description of the place? Well, all the details regarding the square area it occupies, the vast assembly of patients, nurses, officials, workmen, &c., it incloses can be learned by perusing the proper guide-books. These must have been described over and over again and their repetition would weary the initiated reader. To realise the vastness of the place it must be seen. It is a small town in itself. Suffice it to say that its origin dates from 1656 when buildings which were used for the manufacture of saltpetre were transformed by royal edict into wards or dormitories for the "renfermement des pauvres femmes." In 1684 the "Hôpital de la Force" was constructed for the detention of "femmes et filles de mauvaise vie." Successive enlargements in the eighteenth century resulted in the monumental establishment which we see at the present day. The regulation number of beds is stated to be 3812, and many interesting statues (including that of Charcot), monuments, medallions, busts, &c., worthy of attention are to be met with in different parts of the institution. In the salon of the director may be seen a large picture attributed to Mignard (an allegory to the glory of Louis XIV., the founder of the hospice), and in the "Salle des Cours" is a remarkable picture of Tony Robert Fleury represen [illegible] those mentally affected. [illegible] of course, well known, but [illegible] ork of Professor Déjerine who was good enough to induct the visitors into the mysteries of one of his wards. Again it must be admitted that his method of procedure is well known to the neurologists in England. Confirmation of this statement consists in the fact that Dr. Alexander Bruce and Dr. Byrom Bramwell are working on his line of treatment in Edinburgh with marked success. It may be mentioned here that besides the above-mentioned gentlemen, Professor Déjerine was accompanied this morning by Sir William Broadbent, Sir Dyce Duckworth, Dr. C. E. Beevor, Dr. F. W. Mott, Dr. H. Morley Fletcher, Dr. C. S. de Segundo, and others. It is interesting to note that Dr. Huchard, of the Necker Hospital, accompanied the visitors and engaged in friendly passages of arms with Professor Déjerine. After giving a demonstration on some perfect sections of the *entire* cerebrum for microscopic investigation, declaring at the same time that macroscopic work was a thing of attention at the hands of English medical men and nurses is necessarily a source of great comfort. The number of in-patients averages upwards of 300 annually and of out-patients over 2000. The visitors were taken round the wards and their presence excited great interest among the patients who had been looking forward to the occasion. There was no speechmaking beyond the formal welcome extended by the committee and the medical staff, the rest of the time being devoted to inspection of the new operating theatres, the system of accounts, and other technical details. The visitors left with a feeling of great and sincere satisfaction that their fellow countrymen in Paris are so well cared for, thanks to the munificence of the late Sir Richard Wallace.

THE PASTEUR INSTITUTE.

It is a far cry from Levallois-Perret to the rue Dutot, where the buildings of the Pasteur Institute are located, but in motor-cars and carriages the visitors, accompanied by their lady friends, arrived in large numbers—probably in totality—at 3.45 P.M. They were received by the director, Dr. Roux, who we regretted to see did not appear to be in the best of health. After a formal welcome in the library the visitors, together with Sir Francis Bertie, the British Ambassador, and Lady Bertie, Madame Pasteur, and many eminent members of the French medical world, adjourned to the basement where the mausoleum of the great Pasteur is placed—an imposing *caveau* richly adorned with glittering mosaic and illuminated with inscriptions recording the life-long devotion to the pursuit of scientific truth of the great French man of science. Standing with his back to the wrought-iron gates of the tomb Dr. J. Kingston Fowler, speaking as dean of the Medical Faculty of the University of London, delivered an eloquent address in French, enunciated with a purity of accent and a freedom of diction that excited the admiration and surprise of our French hosts. Addressing himself to the Director and to Madame Pasteur, he asked permission to deposit a wreath on the tomb of the great master to whose labours in the cause of science and humanity the institute was a worthy and becoming monument. But it would be a pity to translate into English words that sounded so well in the language in which they were delivered. We give the original.

Monsieur le Directeur,—J'ose croire qu'en ma qualité de Doyen de la Faculté de Médecine de Londres, vous et Madame Pasteur me permettrez de déposer cette couronne sur le tombeau du maitre qui a tant fait pour la science et l'humanité, et dont cet institut même rappelle à l'univers les travaux accomplis. Cet hommage, je le rends au nom des quatre cents professeurs de la Faculté de Médecine, je veux y associer de plus tous ceux qui exercent notre profession, tous ceux qui visitent aujourd'hui ce pays et cette ville dont les traditions artistiques, littéraires et scientifiques sont connues du monde entier. Le souvenir et l'exemple du grand Français que fut Pasteur, inspireront toujours les hommes qui, comme lui, voudront se dévouer à la cause universelle de la science. Les découvertes de Pasteur dans le domaine de la physique et de la chimie, ses recherches à la fois ardentes et patientes, sur les causes de la fermentation, sur les causes des maladies chez l'homme et chez l'animal, ont sauvé d'importantes industries et nous ont permis d'une manière plus efficace et plus sûre non seulement de soulager ceux qui souffrent, mais encore d'arracher à la mort bien des gens qui sans lui auraient péri. Je ne saurais mieux faire que de rappeler l'hommage rendu par un de ses plus éminents disciples, Lister : "Vos brillantes recherches m'ont prouvé l'évidence de la théorie des causes de la putréfaction par les organismes microbiens et m'ont fourni le seul principe sur lequel pouvait être basé le système antiseptique." Le dix-neuvième siècle marquera dans l'histoire par les découvertes de tout genre : les travaux de Pasteur suffiraient seuls à lui assigner une place prépondérante dans les annales de la science.

La science ne reconnait pas de frontières ; elle réunit en une commune fraternité tous ceux qui se devouent à son service. De près ou de loin, tous ceux qui suivent les traces de Pasteur contribuent à rapprocher les peuples. Nous sommes convaincus que l'amitié entre la France et l'Angleterre ne cessera de croitre, que les deux nations travailleront d'un commun effort au progrès de la science et contribueront à la réalisation de ce but : la paix du monde.

The speech met with a cordial and sympathetic reception and was followed by one, also delivered in faultless French, by Dr. Augustus Waller, chief of the laboratories of the University of London, who insisted on the debt that humanity owed to Pasteur for his labours in the study of the infinitely little. Pasteur, indeed, was "*le médecin de la médecine*," in that he taught the medical profession the causes of many of the diseases which they were called upon to treat and incidentally pointed out the means of preventing and of curing them. He claimed that in years to come, when men could form a better conception of the services rendered by Pasteur to science for which we were yet far too near, it would be held that the greatest discovery of the nineteenth century was not steam or electricity but that made public by Pasteur who, in rendering service to France, had rendered incalculable services to humanity at large.

These eloquent periods were warmly applauded and the visitors then paid their homage to the illustrious dead by filing before the tomb.

They then took refreshments in the library where a medal commemorative of the occasion was presented to each visitor, after which they broke up into parties to inspect the various departments, the laboratories, and the Pasteur hospital. The latter lies behind the main block of buildings devoted to chemistry and biology and is now fast approaching completion. This institution, which was founded consequent upon the publicity given to the serum treatment of diphtheria at the Congress of Hygiene at Budapest, is due to the generosity of an anonymous benefactress. It is reserved for the treatment of microbial diseases by Pasteurian methods including, of course, the treatment of hydrophobia. Further funds were provided by Madame de Maillefer in memory of her husband and of her grandfather, Professor Baudelocque, whose memory has also been perpetuated by the celebrated lying-in institution that bears his name. This lady's generosity enabled the managers to install and to equip an out-patient department. The hospital comprises two pavilions, each containing 60 beds, installed on the cubicle system. On entrance the patient is taken into a cloakroom where he changes clothes, his own being taken away for purposes of disinfection. He is placed on a moveable bed and is transported by a lift to the room which he will occupy until convalescent. There is an admirably equipped surgical theatre (operating room) on the first floor. The building is constructed with special attention to the possibility of isolating any one part from the rest. Each room opens on to a spacious balcony which communicates at the angles with the corridors that separate each set of rooms from the others, thus enabling any particular cubicle to be isolated completely and effectually.

The rooms themselves are as aseptic as human ingenuity can contrive. The partitions are glazed to insure a maximum of light and nowhere are there any projections capable of retaining dust. The floor is of glazed stoneware and the non-glazed walls are covered with porcelain tiles. All angles are rounded off and the cleansing is done by copious ablutions, brooms and dusters being rigorously banished. Each room has two doors, on opposite sides, one for the service *viâ* the corridor and the other giving access to the balcony should special isolation be indicated. They are simply furnished, everything being in metal or porcelain. Special rooms are set apart for convalescing patients and on the second floor rooms are reserved for patients accompanied by their relatives. Only one of the pavilions is at present in working order, the completion of the second having been intentionally postponed in order to get the benefit of actual experience in determining its distribution and general arrangements.

The Institut Pasteur, as briefly described, differs from most scientific and medical institutions in France in that its inception, realisation, and maintenance are due to private initiative. As such it affords a valuable object lesson of what can be accomplished by individual effort unaided by the State—a lesson that may not be thrown away on our neighbours across the channel, who have inherited an almost unconquerable tendency to look to the authorities to initiate and to organise all institutions of public importance ; indeed, the possible scope of private initiative was one of the things that most impressed our French *confrères* when they saw in our London hospitals a striking example thereof. There was so much to be seen and admired and so many explanations to be given and received that the visit was a long one ; indeed, by the time it was over it was time to prepare for the banquet that marks the conclusion of a "scientific excursion" that we trust will be fruitful in cementing the friendship between us.

CLINIQUE BAUDELOCQUE.

No visitor interested in obstetrics could fail to avail himself of the exceptional opportunity afforded to study the organisation and the management of the admirable clinique in the Boulevard de Port Royal of which Professor Pinard is the presiding genius. Each morning at 9 o'clock a party crossed Paris with this object in view and were cordially received by the staff. The hospital is an extensive light wooden structure all on the ground floor, well lighted on every hand, with ample provision for ventilation. It contains 110 beds and the visitor is struck at once by the large allowance of floor space allotted to the beds, greatly in excess of that provided in the general hospitals of Paris. The staff, senior and junior, including the students attached to the service, are dressed in brown holland overalls and the most scrupulous cleanliness is everywhere enforced. We may recall that the clinique was instituted some 16 years ago for the express purpose of providing students with facilities for the study of practical obstetrics, and Professor Pinard on his appointment to the newly established chair availed himself of the opportunity to carry into effect certain principles thanks to which the mortality has been gradually reduced until actually it does not exceed 0·3 per cent. (six deaths on an average of 2500 labours).

The visitors had an opportunity of witnessing various gynæcological operations performed by Dr. Faure and of seeing how the *service d'accouchements* is organised. On Friday they assisted at the clinical demonstration conducted by Professor Pinard when the students in charge of recent labours are called upon to render an account of their stewardship *coram populo* and the salient features of each are emphasised for the information of the others. One point on which special stress was laid was the importance of ascertaining the weight of the placenta in all cases of premature labour in order to assist in the determination of the cause of the premature expulsion. The demonstration was followed by a clinical lecture on rupture of the uterus based on a very interesting and instructive case. A young primipara, whose conjugate diameter, carefully and repeatedly measured, was ascertained to be 9·2 centimetres, in the course of a tedious labour suddenly complained of pain at the fundus of the uterus. At the same time the contour of the abdomen was noted to have changed and on careful palpation a sort of gutter could be made out in the uterine wall. The presenting part (the forehead as it turned out) receded and the diagnosis of rupture of the uterus was arrived at, in spite of the fact that the patient's general condition was comparatively satisfactory. The uterus and the fœtus were forthwith removed but the patient succumbed three days later and the anatomical specimens were shown. Professor Pinard attributed rupture to the thinning of the uterine wall caused by the pressure of the forehead plus the disintegrating effect of the œdema which was well marked. At the post-mortem examination it was found that the conjugate diameter was in reality only seven centimetres owing to compression of the pubic rami. The nature of the presentation was masked by an enormous caput succedaneum, otherwise in all probability earlier intervention would have been judged necessary. The impression carried away by the visitors was that, as a school of practical midwifery, the Clinique Baudelocque occupies a foremost place, not only in regard to the wealth of material but also, and especially, in regard to the eminently practical manner in which the instruction is imparted.

HÔPITAL LARIBOISIÈRE.

On Saturday many surgeons visited the Lariboisière Hospital and there saw Professor Hartmann perform hysterectomy and partial gastrectomy. Among this number were Mr. W. H. Battle, Mr. W. Arbuthnot Lane, Mr. W. F. Brook of Swansea, Sir William Macewen, Mr. A. W. Mayo Robson, Mr. James Berry, and many others. Professor Hartmann's theatre was most up to date in its construction and well lighted. There was ample space for the audience so arranged that all could see. The entire wards, theatre, and attendants were some of the smartest seen by the visitors in Paris. A little sign of this smartness and finish was that the binder of the first patient was beautifully embroidered in red with the name of the ward, Civiale. The surgeon and his assistants made their ablutions at basins in the theatre so that all precautions were under the eye of the operator. Professor Hartmann performed the gastrectomy with the patient in a slightly Trendelenburg position. The glands along the lesser curve of the stomach were cleared out as high as the œsophagus when the coronary artery was ligatured. The operation was carried out on the lines recommended in Kocher's "Operative Surgery." The coaptive and hæmostatic and the invaginating sutures were commenced at both ends and when they met in the middle were knotted. Every fourth stitch or so was knotted by passing through the loop of the last stitch. The duodenum was sutured into the posterior surface of the part of the stomach left. Both in this case and the hysterectomy a drainage tube was inserted apparently because in the latter the Fallopian tubes were full of pus and in the former there was some escape of stomach contents. It is interesting to know that so experienced an abdominal surgeon as Professor Hartmann does not hesitate to use drainage whenever it may be at all advisable. Professor Hartmann's technique is marked by great care, neatness, and attention to detail and does not aim at brilliance or speed. A group of surgeons, including Mr. Mayo Robson and Sir William Macewen, paid a visit to M. Poirier's service on Saturday. The wards were decorated with flowers for the occasion—a souvenir of M. Poirier's English visit. They forthwith proceeded to the operating theatre where they witnessed M. Poirier perform a hysterectomy and sundry other operations. Some of the visitors having criticised the number of beds allotted to the wards, M. Poirier explained that accommodation had to be provided as required and that the accommodation available was far short of requirements.

HÔPITAL COCHIN.

The Hôpital Cochin does not appear to have been visited by such large numbers as some of the other hospitals. At the same time it presents several points of interest to which attention may be called. The old building (which is not attractive from the modern point of view and which is gradually being replaced by well-equipped pavilions) was founded in 1780 by M. Jean Denis Cochin, Vicar of St. Jacques-du-Haut-Pas, who expended a portion of his private fortune in its creation. Originally called Hospice Saint Jacques and comprising only a service of 38 beds, after various changes of name it is now known as Hôpital Cochin (after its founder) with a service of 175 beds. It was impossible to devote the time to a thorough exploration of the place so the visitors elected to view the modern "pavilion Potain" where they were received by Dr. Chauffard, the senior physician, who exerted himself thoroughly to make the visit as attractive as possible. It was not long before the fact was borne in upon the visitors that a great deal of work is got through there during the day and that by a judicious division of labour, and by the cheerful and earnest coöperation of the various members of the staff, many valuable observations on the clinical material available are placed on record. Dr. Chauffard himself made the remark that whereas, in his experience, the hospitals in London cater largely for the personal comfort of the patients, in Paris the necessity of utilising all available funds to their full extent results in the production of institutions where the homely appearance of the wards, &c., is subordinated to the effort to obtain every benefit (scientifically considered) from the clinical material presented by the erection and the support of well-equipped laboratories. Thus in one of the pavilions Dr. Chauffard is provided with a small sanctum, adjoining which is a moderately sized laboratory provided with an electrically driven centrifuge, the most modern microtome (Minot), microscopes, chemical reagents, &c., where, it appears, a considerable amount of work is done, notably in the constant and systematic examination of pathological fluids. As in the case of the Boucicaut Hospital, the wards are dome-shaped and the floors are tiled; the latter slope very gently towards a waste plug in the centre of the ward from which the water, which is used every morning in scrubbing down the floors, runs away. The number of beds and cubic content of the wards are marked on the wall near the door thus: 14 beds, 816 cubic metres. There is a moveable bath in each ward. Standing in the centre of the Salle Strauss is a table of about three metres by one metre, made of "lave émaillée," a very strong material with a smooth surface, which is unaltered by powerful reagents such as pure HNO_3. This description applies only to the pavilion which is being modernised, and in this connexion it is interesting to note that the funds for this purpose (500,000 francs) have been voted by the Assistance Publique who obtained the money from a percentage of the takings of the Pari-Mutuel, a self-adjusting betting machine (so to speak) which was instituted on the racecourses after the expulsion of the bookmakers. When the restoration of this hospital is completed the modern physician or surgeon must indeed be hard to please who should express dissatisfaction with its architecture and appointments.

THE BANQUET.

On the evening of Saturday the visit came to a close with a banquet which was held at the Grand Hotel under the presidency of Professor Bouchard. The President of the Republic was represented officially. The British Ambassador, Sir Francis Bertie, was present and nearly 400 covers were laid. The banquet was a difficult matter to organise, for it is not the custom in France to have very large banquets unless they be of a somewhat improptu description. Fortunately, there is a hall for festivals at the Grand Hotel large enough for such an assembly. The staff which the hotel had at its service was also fully capable of coping with so great a service and the varied *ménu*. The wines were all served in due order to match with the dishes for which they were intended. The following is the *ménu* :—

Petite marmite.
Truite saumonée sauce Windsor.
Côtelettes d'agneau aux nouilles.
Cailles en chaufroix à la gelée.
Poularde du Mans truffée.
Salade.
Asperges d'Argenteuil sauce Chantilly.
Mousse glacée Alexandra.
Friandises.
Corbeilles de fruits.

VINS.
Tisane Saint-Marceaux.
Graves supérieur—Médoc vieux.
Château Cantegril—Château d'Isson 1896.
Corton 1889.
Saint Marceaux extra dry.
Café—Liqueurs.

It was printed on paper ornamented with shamrocks, thistles, and roses, gracefully entwined and tied together with a tricolour ribbon. Immediately above the President, and suspended in front of a balcony, were the arms of the Paris Faculty of Medicine in coloured glass and illuminated by electricity. Other suitable decorations, a profusion of flowers, and the beauty of the great hall itself made up a very imposing and brilliant sight. Unfortunately there were no ladies present. It would not have been possible to augment so largely the number of guests ; but, on the other hand, the ladies were all provided with seats at the Grand Opera. The English ladies were formed in groups, each group having a French lady to act as hostess. At the opera the owners of private boxes gave them up and the other boxes were engaged so that all the boxes were filled by English ladies and the French ladies who accompanied them. Never has the Opera House presented so peculiar and graceful an appearance. Not only was there no gloomy male attire in the boxes but the beauty and cheerful colours of the ladies' dresses were further enhanced by the flowers that had been distributed among them. During the *entr'actes* very delicate bonbons were handed round. The performance consisted of the revival of Gluck's opera, *Armide*.

To return to the banquet, by Professor Bouchard's side were seated Lieutenant-Colonel Lamy, representing M. Loubet, President of the Republic, and Sir Francis Bertie, British Ambassador. There were also M. Lepine, prefect of police, and M. Mesureur, director of the poor-relief administration (Assistance Publique), and, naturally, the best known among the British visitors and the French hosts.

At dessert Professor **BOUCHARD** commenced the series of speeches. Unfortunately his voice could only reach those who were sitting quite close to him. He had received a telegram sent to him from Montélim by M. Loubet worded as follows :—

> I keenly regret that to-day I am not able to be in personal communication with the eminent men now gathered together in Paris. I beg you to tell your English and French colleagues that with all my heart I wish them success in their humanitarian task. The relations so happily established at London in 1904 and at Paris at this moment will surely serve to assure progress in the art of relieving human suffering and will contribute to maintain and to develop the cordiality established between two nations that are neighbours and friends.
>
> EMILE LOUBET.

This message was naturally greeted with very loud cheers, but the applause was still greater when Professor Bouchard further announced that he had been instructed by the President of the Republic to confer on Sir William Broadbent the Cross and Insignia of Commander of the Legion of Honour. Sir William Broadbent was called upon to stand up. Professor Bouchard then fastened the bright and much-coveted red ribbon round his neck, and embraced the new knight of this the greatest of French Orders. The band of the 24th Regiment of Infantry struck up the British National Anthem and the greatest enthusiasm prevailed. Professor Bouchard seized the opportunity to invite all present to drink the health of President Loubet and that of His Majesty King Edward, which was done with a fresh outburst of enthusiasm.

Professor Bouchard now strove, amid much noise and excitement, to conclude his speech. After alluding to the great discoveries of Jenner, Lister, and Pasteur, he said: "These are conquests that are more precious than those accomplished by the force of arms. Domination is one thing, moral domination is quite another matter—that which has for weapon but the light of truth and for means of action but the force of persuasion. In this magistrature of universal moral government we do not surrender the part which is ours and which is constantly increasing. The great medical discoveries achieved in both our countries are not foreign to the moral credit we enjoy. The peoples know what services we have rendered them. Consequently they will listen to us when in politics we press upon them words of justice and ask them to accept counsels of peace." Then alluding to the visit to the mansion which a prince of the House of Orleans had bestowed on the institute, Professor Bouchard said: "For long have the oppressed looked towards France and it is on the coast of England that the conquered in our civil discords and the princes in exile have found a safe refuge. Yesterday you admired at Chantilly the marvels which a sumptuous prince had accumulated. He was thus able to return to you some of the hospitality he had received in your country."

Sir **WILLIAM BROADBENT** now rose to reply, but he was heard no better than the previous speaker. Therefore as only a few persons sitting close by could hear the others indulged in whispered conversation and this rendered it still more difficult to follow the speech. The same difficulty arose in regard to most of the speeches. Sir William Broadbent offered his thanks for the eloquent words that had been spoken. He thanked his colleagues of England and France for the enthusiasm with which they had greeted all allusions to the friendship of the two nations. After three such memorable days culminating in the great honour that had most unexpectedly been bestowed upon him by the President of the Republic through the intermediary of his friend, Professor Bouchard, he felt overwhelmed and could not find adequate expressions to describe his delight and gratitude. He then enumerated the various great receptions, that of the Faculty of Medicine, the resplendent scene at the Hôtel de Ville, the beauties of Chantilly, the theatrical representations at the Automobile Club, and everywhere the same cordiality, the same desire to see the two nations draw closer to each other. He could not but wonder at all this, particularly when he thought that it was all in honour not of some great potentate but simply for the sake of a few medical men. "This is how kings are received," said Sir William Broadbent ; "you could not have done better for Edward the Pacificator who so loves us and loves you with us." At the Pasteur Institute and elsewhere he had heard speeches the memory of which he would always recall with pride. Their deepest emotion was experienced at the tomb of Pasteur, for his name was ever on their lips. And had not Pasteur preached the great gospel of Labour and Peace? But some sceptics might inquire what, after all, could the three days do in the history of the world. He was convinced that they had served to forge a link in the chain. Formerly chains were made with blows from great hammers. Now they were soldered with electric currents, but in their hearts and minds they possessed that which was stronger even than electricity.

Many cheers followed this speech and much was the surprise of the British visitors when the band struck up, "For he's a jolly good fellow."

Professor **DEBOVE**, dean of the Paris Faculty of Medicine, now spoke. He argued that there was nothing very remarkable in the fact that persons who belonged to the same profession should dine together. But when they considered how numerous they were, when they observed their unity of purpose and the spontaneous character of their demonstration then its importance became evident. That was even more evident when the fact was added that there had been no official instigation. They must then recognise that the force of attraction must indeed have been most powerful to bring about so imposing, so magnificent a result. Nothing had held them back, neither the distance, the lack of time, nor the sea that had to be crossed. It was by the force of circumstances that their speeches assumed a political tone This resulted from the good understanding between the two countries and from the peculiar situation in which medical men were placed They were compelled to take part in the private life of all classes of the community, therefore they were best able to make an impression and to insure that the voice of reason should be heard The medical practitioner was in a good position to recall the fact that there was a moral law governing the relations of nations with each other and that free peoples should unite to enforce its due observance. Thus united by the same love of science, by the desire to see justice and concord prevail, they could say that if their lips spoke different languages their hearts had but one desire

Professor CLIFFORD ALLBUTT replied and said that if in the manipulation of words they had fallen short of the exigencies of the situation their feelings were none the less keen and sincere

Dr P H PYE SMITH spoke in French and in English, recalling his experiences as a student in Paris

Dr STRAUSS, Government Military Inspector of the Paris Garrison, alluded to the services of the military surgeons of England, such as Hunter, Pringle, Longmore, and others Their works were known and highly appreciated in France

Surgeon General KEOGH replied that he had found that the great traditions left by Baron Larrey, the chief surgeon of the armies of Napoleon I, were still piously preserved and remained as an example of what the military medical service should be He then alluded to Paris as the capital of a country loved and admired throughout the world and spoke of the joy that all

Dr J e

receptio s

in French and the other half in English He dealt on the fact that if medical men were patriots their scientific studies helped to lift them above any narrow and prejudiced form of patriotism

Sir WILLIAM MACEWEN replied in English, and declared that even so he could not express all his gratitude He alluded to the glories of Broca, Charcot, and Pasteur, who had laid the foundation of new schools

Dr BALZER, president of the Medical Society consisting of the staff of the different hospitals, explained the organisation of this body and its sympathy with the *entente cordiale*

Dr BRUCHET spoke as president of the council of the Society of District Practitioners He represented the democracy of the medical profession Their endeavour was to maintain unity within the ranks of the profession and to give to the weak and poor practitioner the strength derived from union and organisation He raised his glass to the health of the general practitioners of England

Dr GEORGE OGILVIE'S amusing and thoroughly French speech should be given as he spoke it —

Monsieur le Président Messieurs, he said, mes paroles ce soir sortent difficilement Je ne suis pas à mon aise, ni dans mon assiette—excusez l expression, messieurs Je me sens un peu timide, non parce que je parle devant vous, Monsieur le Président devant l élite

mais parce que c est la première

m exprimer en langue française depuis q

de la Légion d Honneur Je suis très

tinction, et je l apprécie d'autant plus, qu'elle me vient de la France Messieurs, ce soir j ai la tête aussi pleine d idées que la ruche est pleine d'abeilles et ces idées ont autant d envie de sortir que la reine des abeilles en a de s échapper pour prendre son vol nuptial au mois de juin Mais cependant je crains bien que votre hospitalite française n ait apporté un peu de trouble dans mes idées, et maintenant je ne rends

mon pays natal, le pays de Marie Stuart, un petit pays qui n'est pas tout à fait inconnu dans le vôtre, et dont Boieldieu a chanté l hospitalité dans la Dame Blanche Le maire d une ville avait rencontré au marché le maire d une ville voisine, et l'avait invité à diner Le diner fut simple, mais copieux, et abondamment arrosé de vin capiteux Au moment de se séparer, en reconduisant son invité à la porte, l'hôte lui dit *prenez garde aux marches*, cet escalier est un vrai casse cou, et quand vous arriverez au bas, vous verrez deux voitures—prenez la premiere, car la deuxième n est pas là Voilà, messieurs, l hospitalité écossaise, et j'espère que la votre n'aura pas le même effet sur vos invités Je ne crains rien pour moi même, car je suis habitué à l hospitalité française Je m'aperçois, messieurs—par les rires de l assistance—que l humour écossais va de pair avec l'esprit gaulois, c'est comme le champagne sec, it faut avoir un goût cultivé pour l'apprécier Messieurs, nous sommes à Paris, et nos quatre jours ont passé comme un eclair Il n'y a pas d étrangers qui vraiment connaissent Paris Vos magnifiques boulevards, les musées du Louvre, les Champs Elysées, les Invalides, ne sont qu'une petite partie de Paris *Pour être capable d'apprécier le* charme et la beauté de la ville lumiere il faut être un mélange de savant, de *philosophe*, et de boheme Suivre les pâles rayons de la lune éclairant la magnificence solennelle de Notre Dame, et la longue ligne d édifices qui s'étend de la Sainte Chapelle aux Tuileries Se tenir sur le Pont Neuf, quand les lampes jettent leur lueur blafarde sur les eaux agitées de la Seine, et assister à la lutte entre le soleil et les ténèbres Parcourir les boulevards silencieux pendant que la cité est endormie Ecouter le bourdonnement de la ruche à son réveil Flâner dans les rues du Quartier Latin, où chaque pierre évoque des souvenirs S asseoir dans un petit café, dans une rue étroite, au milieu d artistes atteints de cette maladie splendide—le génie Voilà ce qui est voir et connaitre *Paris Incomparable* cité! Enfantée par la nature, vénérable par l'âge, mais toujours jeune Pour la célébrer, il suffit d'exprimer ce qu elle est, le monument et le foyer d un grand *peuple* Que dire de votre école de médecine, de vos hôpitaux, et de tous vos géants du passé—Louis, Trousseau, et Pasteur, qui ont fait jaillir la lumiere des ténèbres—Larrey, Dupuytren, et Nélaton, qui ont mis de l'ordre, là ou était le chaos, et j en passe, je ne parle que des morts, car il m en faudrait citer trop de vivants Puissent ces génies nous servir à tous d exemple dans la recherche de la vérité, suivant ce que disait Rousseau dans Emile—" Je *sais que* la vérité est dans les choses et non dans mon esprit qui les

de rendre le petit coin de l'univers où nous vivons plus humain, plus sage, et plus heureux Tout à mon admiration pour votre magnifique cité, et à mon affection pour vos géants du passé j allais presque oublier, Messieurs, de remercier les vivants pour leur splendide réception Que puis je dire sinon, merci à tous, millefois merci Chacun de vous a été si gentil pour nous qu'il m'est impossible de vous nommer tous Pendant qu il me soit permis de citer un nom, celui du Dr Triboulet, dont l'esprit d'organisation, et l'amabilite ont assuré le succès de cette fête cordiale Messieurs permettez moi de vous présenter, au nom de mes compatriotes, nos plus sincères remerciements—et ils partent du cœur—pour cette visite, qui vivra à jamais en notre mémoire Messieurs je crains d'avoir trop parlé, de vous avoir ennuyés, peut etre mon imagination a t-elle pris le mors aux dents? Ce n est pas ma faute, c est la faute de ma nationalite car quand l imagination s'empare d'un Ecossais, elle le possède dans le vieux sens biblique du mot, c est comme un volcan, que rien ne peut éteindre Encore un mot, Messieurs A Québec, au Canada, reposent dans le même

un héros français, un héros anglais,

Ils ont lutté tous deux sur le même

s ont perdu leur vie pour leur pays Ils

côte à côte, leur dernier sommeil, honorés

également par l'Angleterre et par la France Messieurs, dans les âges futurs si on élève un monument à la France et à l Angleterre, je souhaite qu'on lise sur son socle—La France et l'Angleterre unies pour le progrès et pour la paix

Dr MONPROFIT spoke on behalf of the French provincial physicians and surgeons and after a few words from Mr LYNN THOMAS the long series of toasts came to an end

The dinner was the formal close of the meeting, after which the English visitors departed in two groups to visit Vichy, Lyons, Evian and Geneva, *or Biarritz and Caen*

As well as the formal functions and receptions we must notice in a few words the individual hospitality of our French hosts This was of the most lavish description, in fact they all kept open house for their guests from Great Britain, the cordiality of the welcome being enhanced by the graceful tactfulness of the French ladies Those who know how rigidly separate the French home life is kept *from* the life of affairs will understand that our French *confreres* were thus conferring upon their visitors a high compliment It is quite impossible to chronicle all the festivities prepared by our kind hosts in their own homes, but amongst the French medical men who entertained were Dr Bouchard, Dr Lucas Championniere, Dr Huchard, Dr Raoul Blondel, Dr. Landouzy, Dr Marie, and Dr Carré.

THE LANCET.

LONDON: SATURDAY, MAY 20, 1905.

The Financial Relations of the London Hospitals and their Medical Schools.

WE publish this week an address dealing with the financial relations that exist between the London hospitals and their associated medical schools by Mr. HENRY MORRIS, the representative of the Royal College of Surgeons of England upon the General Medical Council and senior surgeon to the Middlesex Hospital, who has studied the bearing of these relations with particular closeness. Mr. MORRIS fairly and forcibly puts his views upon a situation which is so familiar to our readers that it needs only the briefest *résumé* here. It is sufficient to say that the greater number of the medical schools of the metropolis are no longer self-supporting and that as a result they are, or have been, in greater or less measure subsidised by the hospitals. Into this matter a committee was appointed by King Edward's Hospital Fund to inquire, with the result that it reported that at least eight metropolitan medical schools have received pecuniary support from funds which should strictly have been devoted to the maintenance of the hospitals although at most or all of the schools the teachers have during the last decade done their work for practically no salaries, thus reducing expenditure to the utmost. This position—one, we would point out, entailing upon the medical teachers of the metropolis an amount of self-sacrifice which is very inadequately recognised—has been brought about, without entering into details, by two circumstances. The first is the increased cost of medical education and the second is the increased popularity of the provincial medical schools which are supported by students who until recently came as a matter of course "to walk" one of the London hospitals. The committee of the King's Fund, in making clear the unfortunate financial position, in no sense regarded the assistance given by the hospitals to the medical schools as constituting a vicious diversion of funds or an immoral breach of trust but it came strongly to the conclusion that for the future the moneys received for medical education and those received for the maintenance of the hospital must be kept separate. As a comment upon the bad economy of the arrangements for medical education which necessitated the keeping of 12 separate foci for instruction in the elementary and ancillary scientific branches Sir EDWARD FRY'S committee warmly endorsed the plan of the University of London for starting a Medical Institute for the centralised teaching of such subjects. Such is, in brief, the admitted position and Mr. MORRIS'S oration amounts to a distinct opposition to the views of Sir EDWARD FRY'S committee. Mr. MORRIS recognises the plight of the schools perfectly but he does not agree that a central school would have the result of relieving or improving it.

In the first place, Mr. MORRIS considers that medical education resulting in exact knowledge, and hence in scientific treatment, was, or should have been, one of the objects of the benefactors of hospitals, so that the question of immoral diversion of funds he does not consider to arise. But we must all see the necessity for medical charity to be above suspicion. We must be able to close the mouth of criticism whether honest or whether merely posing as care for the public weal, and the only way in which this can be effected is by rigidly keeping the hospital moneys for the support of the hospital. Mr. MORRIS points out that the hospitals owe more to the medical schools than the medical schools owe to the hospitals; and in a sense this is undoubtedly true, but if it is not absolutely sure that the hospitals have the power to pay the debt they must not be allowed to make the attempt. Nor is it any excuse for irregular finance to plead that the irregularity is only a little one. The amount paid by the hospitals to the medical schools is relatively very small when the huge outgoings of the big general hospitals are considered, and even the handsome contributions made to hospital expenses by the King's Fund only meet a small percentage of the absolutely unavoidable expenses. Still, it is clear that no hospital should run counter to the wishes of the King's Fund, for this Fund and the Metropolitan Hospital Sunday Fund represent order and organisation in medical charity, and as such are regarded as public safeguards. So that for the future the medical schools of the metropolis, with a continually dropping list of entries, will receive nothing save the students' fees for their support unless they can promptly institute special school funds. This is the course which Mr. MORRIS recommends should be taken rather than the adoption of the centralisation scheme of the University of London, for that scheme he finds absolutely uneconomical, unscientific, and impracticable. He points out that the central institute is not yet built, that it will cost an enormous sum to build it and another to endow it, and the result must be, he thinks, that in the end the medical student would require considerably more money per head to educate him than he now costs. Mr. MORRIS argues with conviction that anatomy and physiology should never be divorced from the general study of disease, as a knowledge of these subjects remains, and must always remain, an integral part of the practice of medicine, he dwells on the vast size of London as an obstacle to the utility of a central medical institution to be placed in South Kensington, and he pertinently asks what is to be done now, as it is evident that the central institution, whatever its success may be when it is a going concern, will not be ready to do its work for some time.

Our readers know that we favour strongly the idea of a central institution and although Mr. MORRIS'S position is in many respects a strong one—and everyone should read his address and learn for himself how forcibly the situation can be described *from the other* side—he has not been able to alter our view. It seems to us that there will be a most valuable economy of labour by teaching all the preliminary medical studies at a central institute, in time there will, we believe, be also a saving of money, and medical education will be improved much in all its later stages by the more orderly and satisfactory grounding that the students will receive. The vastness of London can be got over by having more than one amalgamated school and the difficulties owing to the delay that must occur before the central institute, as devised by the University of London, is in working order can probably also be met by the use of temporary sub-centres. But these are matters on which the medical profession ought now to be receiving more information from those actually interested in the promotion of the central institute. The arrangements by which sub-centres could do the work of the central institute for the time being ought to be arrived at soon and the medical schools of the metropolis ought to know their individual chances under such a temporary scheme. The sub-centres would have their quarters at existing medical schools and the other medical schools ought to know as soon as possible what steps will be taken to safeguard their property in their pupils. The movement for concentration has actually commenced with the transfer by Westminster Hospital Medical School of their students to King's College Medical School for instruction in the subjects of the preliminary and intermediate examinations. An arrangement has been made by which the students will remain students of Westminster, which is satisfactory hearing. The unrivalled clinical teaching in the wards of the London hospitals must not be jeopardised by the retention as permanent students at two or three centres of all the attendants at the scientific classes.

◆

The Relation of Milk Depôts to the Public Health.

IT is a strange satire upon preventive medicine to have to admit that although our general death-rate has undergone, and is still undergoing, a steady decline our infantile mortality should show not only no substantial fall but even in some instances a tendency to rise. It is difficult to believe that none of the forces which have been associated with the reduction of the general mortality should have been without influence upon our infantile mortality, to admit, in fact, that the improved well-being of the poorer classes, their better housing, their higher wages, their improved water- and air-supply, and the better regulation of refuse collection, should, in so far as the infants are concerned, be without effect, more especially when to these considerations we have to add over a quarter of a century of compulsory education. Still, if we claim such good results we are apparently compelled to conclude that this increased well-being has brought with it fresh forces which entirely, and in some cases more than, counterbalance the good, in so far at least as the infants of the working classes are concerned. Probably, however, this is a sound conclusion, and in a measure the increased prevalence of urban conditions, the disinclination and, at times, inability of mothers to suckle their young, female labour, and the diffusion of cheap brands of skimmed milk and of artificial foods are counteracting the improvements which obtain in other respects. In short, the high infantile mortality of the present day is an exceedingly complex matter and is the result of many forces. Those, therefore, who seek to attribute it entirely to an unwholesome milk-supply are eminently unscientific persons who must be classed with those who seek "to stamp out" pulmonary tuberculosis by the use of sanatoriums alone. But, this notwithstanding, there can be no reasonable doubt that a very substantial share in the causation of infantile mortality, more especially during the hot months of the year, must be claimed for the unwholesome milk which is supplied to the children of the poor, and it is this knowledge which is inducing some of our large towns to embark on the establishment and the maintenance of milk depôts, a name which at the present time is largely synonymous with the supply of sterilised or at least pasteurised milk. We are anxious, however, in this article to point out that the supply of sterilised or pasteurised milk is, or should be, but a very small portion of a municipal milk-supply, and it is that portion of it which could perhaps be most easily dispensed with. We are, indeed, very glad to see that Dr. G. F. MCCLEARY, whose milk depôt in Battersea is known to a large section of the medical profession as well as of the public, has lately drawn attention to this aspect of the question both in his work on "Infantile Mortality and Milk Depôts" and in an admirable paper which he read in February last before the Society of Medical Officers of Health. In that paper Dr. MCCLEARY expresses the opinion that "any methods having for their object the purification or quasi-purification in the city of milk already polluted in the country—such methods as sterilisation, pasteurisation, centrifugalisation, or filtration—must be regarded merely as makeshifts to be abandoned when better methods become practicable." This is in our view a thoroughly sound and statesmanlike position and it is one with which apparently Dr. GEORGE NEWMAN, the medical officer of health of Finsbury, who has lately taken part in the organisation of a depôt in Finsbury on the lines of some of the French depôts, entirely agrees.

It can, of course, hardly be seriously urged that nature has intended the young of one species to be nourished by the modified milk of another species and, assuming that the mother be healthy and able to suckle her young, she should be strongly urged, more particularly by her medical adviser, to do so rather than to shirk her responsibilities by procuring modified cows' milk at the municipal depôt, and the promoters of such depôts should use every legitimate means of bringing home to the mother her responsibilities to her child and to the State. In fact, this education of the mothers of newly born infants should be one of the most important functions of every sanitary authority and the milk of the depôt should only be employed, as a rule, as a *pis aller*. This is in no sense equivalent to an argument that such institutions are unnecessary; indeed, in our view there should be such an institution in connexion with every urban district, as also well-trained female inspectors to control the use, and to prevent the abuse, of the milk. But such a depôt should not only supply sterilised or pasteurised milk but also fresh, pure, whole milk drawn and kept under the most wholesome conditions. There are, too, obvious advantages in supplying such milk in sealed bottles. The homes of the poor and the habits of the inmates are such as to render it almost impossible to protect the milk against home contamination and it is this contamination which has a decided influence in maintaining the high infantile mortality.

Some of the advantages of a municipal supply of milk may be gathered from the fifth paragraph of the Battersea contract, which specifies not only that the milk shall be of proper composition but that it shall be drawn from healthy cows and be free from chemical preservatives and colouring matter. The members of the medical profession in Battersea have, too, borne almost unanimous testimony to the value of this milk and their evidence is certainly of more value than much statistical matter. Great, however, as are the advantages of these municipal depôts, more particularly perhaps in an educational aspect, their influence as yet in relation to the total population is likely to be but small. In order that a general reform may be brought about it is necessary that there should take place an awakening of the public health conscience in the matter of better milk control. What is wanted is a record for the enlightenment of the public of the conditions which are actually found in the vast majority of the cowsheds in this country, where there are deficient light, defective ventilation, and bad drainage, and where neither the cows' udders nor the milker's hands are washed. The Liverpool and Manchester milk clauses which give these towns, under certain conditions, control over the cowsheds, and so on, outside the city from which milk is supplied to the inhabitants are admirable, but unless our rural districts will recognise their responsibilities the town dweller will continue for some time to come to imbibe unwholesome concoctions for milk. It is true that, as Dr. McCleary points out, our county councils might take more action in the matter but, unfortunately, the past history of county councils in this direction does not hold out much hope that reform will come from this quarter. For ourselves we should be glad to see a survey undertaken by the medical department of the Local Government Board of some of the cowsheds in each county and a report made, accompanied by illustrations, of the conditions actually found to exist. In this way we might hope to see some awakening of the public health conscience in rural districts. In the meantime it is satisfactory to note that the Local Government Board for Scotland has recently issued some model regulations relating to dairies, cowsheds, and milkshops which in several particulars are in advance of those issued by the Local Government Board for England and Wales. In the past it is possible that too much attention, relatively, has been paid to the prevention of the spread of certain infectious diseases through the agency of milk, but having regard to the influence of impure milk upon infantile mortality a general attack upon darkness and filthy methods in the cowsheds of this country might be expected to yield an equally abundant harvest. The milk should be drawn from healthy cows in the open field where practicable, the udders of the cows and the hands of the milkers should be carefully washed prior to each milking, and the milk should be forthwith strained and cooled and sent to its destination in sealed cans in vans so constructed as to keep the milk at the lowest temperature practicable during the transit. If this were done the necessity for sterilisation at the depôts would be materially diminished and pasteurisation at the farm might entirely do away with such necessity. At present, however, sterilisation or pasteurisation is in many instances absolutely necessary for the satisfactory working of the depôts, more especially during hot weather, and the statistics furnished by Liverpool and other places, although obviously open to criticism, are such as to point to the conclusion that material benefit accrues in the homes of the poor from the employment of such milk.

The Pathology of Epilepsy.

Much has been written concerning the pathology and the etiology of epilepsy but these questions cannot be said yet to have passed the stage of surmise. The name of Dr. J. Hughlings Jackson has become indelibly associated with the phenomena of convulsions provoked by certain lesions in the motor area, but in discussing the pathology of "epilepsy" that of the idiopathic form is usually understood and it is in this sense that we use the term here. Inheritance plays a prominent part in the etiology of this condition and the morbid state has been supposed to consist of some minute alteration in the chemical constitution of the grey matter of the brain. The recurrent "nerve storms" which constitute the disease have not, however, been adequately explained and no characteristic macroscopical or microscopical changes have yet been described.

In the *Journal of the American Medical Association* of April 29th Dr. B. Onuf reports the results of necropsies on the bodies of 16 patients who had suffered from epilepsy at the New York State Institution for Epileptics. In 12 cases there were valvular changes of the heart, most frequently of the mitral valve (80 per cent.). Lesions of the aortic valve were less frequent and alterations of the tricuspid valve were still more uncommon. Dr. Onuf considers these lesions as secondary results of the special strain induced by the major epileptic attacks. The cardiac conditions thus described are significant, for it is well known that a patient who is the subject of bradycardia may exhibit epileptiform attacks, and as bradycardia may result from changes in the myocardium it would be interesting to know whether any myocardial changes were noticed in the cases examined by Dr. Onuf. Capillary changes, tortuosity of the vessels, and aneurysmal dilations were observed in several cases and were also attributed to strain. In eight of the cases in which the lungs were examined acute pneumonia was found as a contributory cause of death. The cerebral changes are stated to have been very striking. In ten cases there was a marked thickening of the pia mater over the fronto-parietal lobe. In other cases there were vascular lesions—circumscribed atrophy of one frontal lobe, subdural hæmorrhage (one case), internal hydrocephalus (one case), cerebellar cyst (one case), and shrinkage of the convolutions of the vermis and adjoining cortex (three cases). The most marked changes, however, were noted in the thalamic region. These were of the nature of atrophy, sometimes the pulvinar, sometimes the other, portions being most notably affected. There was also an apparent discrepancy in the proportions of the geniculate bodies. Dr. Onuf discusses the possible relations of these thalamic changes to the epilepsy but he does not venture to express an opinion as to whether they are directly connected with the attacks or are only part of a general pathological condition of the brain. He suggests that there was probably optic atrophy in some of these cases and therefore he lays stress on the importance of an examination of the fundus in patients suffering from epilepsy. Such marked changes as Dr. ONUF describes have not been recorded by observers in this country.

Sir WILLIAM GOWERS[1] has made some valuable comments on this subject which support Dr. ONUF in the reserve which he rightly maintains in the conclusions which are to be drawn from the results of his examinations. Sir WILLIAM GOWERS points out that the "instability" of the cerebral motor functions, instead of being solely due to alterations in the chemical constitution of the grey matter, may be the result of obvious disease. It is not indeed due to disease that can be seen in the damaged part, but beyond the visible disease, whatever its nature, is a zone of altered nerve tissue in which the slightness of the change permits activity in altered form. In such cases the morbid discharges constituting epilepsy may take place. Arising locally, they spread through the brain according to their energy and then leave a tendency to repetition which involves parts unaffected by the primary disease. The same writer proceeds to state that, although it is not customary (as we mentioned above) to include under the term "epilepsy" active progressive brain disease, such as a tumour, even though it cause epileptiform convulsions, yet there is a large class of cases of considerable interest in connexion with organic disease. In these instances there is an old spot of disease which induces the nervous discharges which may be slight or local at first but may spread when more intense and ultimately leave a general disposition which may hardly be distinguishable from idiopathic epilepsy. Some of Dr. ONUF'S cases may perhaps be placed under this heading. His observations are well worthy of note but whether the records have added materially to the present pathology of epilepsy is open to doubt nor does he advance any claim of this nature. That so many and varied morbid conditions were found in the cases which he examined accentuates the difficulty that is experienced in arriving at any definite conclusion as to the precise pathology and morbid anatomy of epilepsy.

Some Considerations connected with the Relative Immunity of the Japanese Armies from Typhoid Fever.

AMONGST the many points that have served to rivet public attention on the stupendous war in the Far East none has done so more, perhaps, than the signal success which has attended the efforts of the Japanese in dealing with the so-called preventable diseases of armies in the field. It is notorious that in every great war of history disease has proved a most treacherous and dangerous foe and has given rise to far greater losses than have arisen from the wounds and casualties caused by the weapons of the belligerents. With the Japanese the case has, however, been different; they have succeeded in minimising the losses from disease and in obtaining results in this respect which have not been hitherto attained by other nations in war. All who have dealt with the medical history of this war have borne testimony to the admirable organisation of the Japanese and to the thoroughness with which every detail connected with their sanitary and medical arrangements has been thought out beforehand, as well as to the skill displayed in practically adapting these to the end in view. The striking statistical results which have been published have called attention to the success that has attended their efforts. These results as regards the greatly decreased scale of sickness and mortality which they set forth are in striking contrast with the experience of Europe and the United States of America in modern war. Are these results to be ascribed solely to the efficiency of the Japanese sanitary and medical systems or have there been any other factors or contributory causes at work in the case of the Japanese armies in Manchuria which have also to be taken into account?

In order to illustrate the point which we are more especially seeking to elucidate let us take the most important disease of modern war, typhoid fever. It is the scourge of European armies operating in the field, especially, perhaps, in the case of operations conducted in hot climates, and the United States in their recent war had the same experience. It has been said that typhoid fever has no geography: it is ubiquitous. The typhoid bacillus, about which and its life-history our knowledge has of late years become so much more extended and precise, is far more widely distributed in nature than is generally imagined. It is no longer to be maintained that this fever is an exclusively water-borne disease, although sudden and rapidly spreading epidemic outbreaks of it are, no doubt, more readily explicable in that than in any other way. But the investigations made after the Spanish-American war into the causes of that fever in the vast camps occupied by the United States troops, together with those of a German scientific commission of later date and the results of experimental observations in this country, have tended to enlarge our views about the existence of vehicles and sources of infection other than water, of a direct and indirect nature. In the case of the Japanese armies it is very important to note that, in addition to the great attention paid to sanitation, typhoid fever is treated as a contagious disease and the sufferers from it are carefully isolated. It is difficult to understand how in this way the dissemination of the bacillus can be prevented altogether, considering the length of time during which it may be detected in the urine, but possibly some of the immunity enjoyed by the Japanese has been due to these laudable precautions. Race, however, has probably played a part in this immunity. Without dwelling unduly upon the influence of race it has, nevertheless, to be recognised as a matter of ordinary observation and experience that Asiatics, native races and those indigenous to the soil, possess a relative immunity, real or acquired, from the diseases common to their own climate, as compared with European and other immigrant races foreign to it. It may be that such immunity in the case of typhoid fever, for example, is attributable to the fact that the natives have in infancy or early life paid their tribute to that disease or it may be that from the nature of their environing conditions they become possessed of an acquired tolerance rendering them immune. But may it not also be suggested that the relative immunity of Asiatics in general, and of the Japanese soldier in particular, from typhoid fever is not so much attributable to any racial as to physiological differences from the European owing to the nature of his food and his habits and customs?

---

[1] Professor Allbutt's System of Medicine, vol. ii., p. 761.

The typhoid bacillus may find a most unfavourable soil for its growth and development in the graminivorous, rice-eating Japanese soldier, as compared with that to be found in the body of the flesh-feeding European, for example, whose diet so largely consists of meat and alcohol in some form or other. The bacterial intestinal flora may be very different in the two cases. An effort has been made in India of late to solve the problem as to the prevalence or not of typhoid fever among its native populations by means of the serum agglutination and sedimentation reaction test, with the result that typhoid fever is believed to be more common among the natives of India, and especially among native children, than has been supposed. Still, there cannot be any doubt that the prevalence and the mortality from this form of fever among the natives, as tested by ordinary Indian experience and corroborated by the records of the native army and jail population, are quite insignificant as compared with what obtains in the European army serving in that country; to which it may be added that the cases of typhoid fever which do occur in the native army are mainly among the Gurkha troops who are meat-eaters and spirit-drinkers. Moreover, from what is known of the well-nigh universal habits of the native population in regard to fæcal contamination of the soil the amount of typhoid fever among them should be proportionately large if their excreta were sowing the soil with its bacillus. There are no sewers in the plains of India and, speaking generally, next to none in the East or in subtropical climates, consequently the inhabitants are compelled to have recourse to the soil for the disposal of their excreta. In the case of the native jails in India this has long been done without having been found to cause outbreaks of typhoid fever in the jail population. The adoption of a dry-earth system, on the other hand, may be, and probably is, a dangerous method for the disposal of fæces in the case of communities so liable to typhoid fever as European soldiers have always shown themselves to be when living under the conditions of field service—presumably because of the risk of introduction of the bacillus to susceptible hosts. Assuming, as we must do in our present state of knowledge, that the typhoid bacillus is veritably and indeed the cause of that disease, the problem may be summarised in the following questions: To what is the relative immunity of Eastern peoples from typhoid fever due, and has such an immunity played any part in the case of the Japanese armies operating in Manchuria? If this latter question be answered in the affirmative, it may be suggested as a subject for further inquiry whether this relative immunity from, or insusceptibility to, typhoid fever on their part, as compared with our experience in the case of European armies generally, is attributable in any way to their environing conditions, and especially to their system of dietary. These questions cannot be answered definitely without exhaustive and statistical examination of the available evidence, but we may be permitted to surmise that the diet of the Japanese, no less than their admirable tactics of precaution, has saved them from the scourge of typhoid fever.

Annotations.

"Ne quid nimis."

THE INFLUENCE OF TRADITION ON MEDICAL PRACTICE.

At a meeting of the Manchester Medico-Ethical Association held on April 18th Dr. S. Holgate Owen opened a discussion on *the Influence of Tradition on Medical Practice.* He pointed out that it was extremely difficult to judge correctly of tendencies in any social or scientific organisation when viewed within a short space of time but that, as regards the organised practice of medicine, the trend of method had, during the past 30 years, undergone a change which was almost revolutionary. The wider the range of survey the more it was found that fixed principles, established rules, and uniform systems, or what used to be called "orthodoxy," were becoming uncertain as guides and less influential upon the minds and the action of medical men. In the midst of this apparent instability, and, as if to taunt us with our want of light and guidance, there came to us from many parts of the world, but especially from America, drugs of all descriptions suitable for all complaints and said to be absolutely certain in their curative effects. This absence of systemisation might be observed in all countries. France, Germany, and America seemed to be devoid of any authoritative teaching in the medical art; there was no medical school or society anywhere which at the present time could agree to promulgate any system or mode of treatment which could be influential beyond its immediate surroundings or for any length of time. Scholasticism, indeed, had received its death-blow, but only within a century ago. Although medicine had now asserted for itself a position among the sciences, it must be remembered that traditional influence had held universal sway for nearly 2000 years—namely, from the time of Hippocrates to the beginning of the seventeenth century, the period of William Harvey and Thomas Sydenham, when scientific discovery began to lay the ghosts of superstition and dogma. The spirit of dogma, however, survived to the beginning of the nineteenth century. At the present juncture social and scientific developments were taking place which were influencing the practice and, Dr. Owen believed, the status of the medical man. The rapid advance which public sanitation, domestic sanitation, and personal hygiene were making, on scientific lines, was forcing its way at the urgent demand of a social development unprecedented in rapidity and intellectual breadth at any previous period of our history. The problem which now faced us every day was less frequently, What are we to give to cure a disease, and more commonly, How are we to correct the error of life through which it has arisen and to prevent its occurrence?

HOSPITALS AND THE WELL-TO-DO.

In a recent case heard by Mr. Justice Darling and a common jury Mr. Bale, a tailor, sued the London County Council for damages for personal injuries and for damage to a trap received through a collision with a tram-car in the Camberwell-road. Mr. Bale was awarded £314 and Mr. Justice Darling, in alluding to the particulars of special damage, said that he noticed that the plaintiff had been treated at St. Thomas's Hospital. He did not, however, see that any payment had been made to that institution. Mr. Bale was a well-to-do man and could afford to pay something. Hospitals were intended in the first place for persons in need. The plaintiff's counsel promised that his lordship's suggestion should receive attention. We do not object to Mr. Bale having been treated at the hospital, for his injuries may have been of such a nature that it was wiser not to convey him home, but we cordially agree with Mr. Justice Darling's remarks. Seeing that Mr. Bale's solatium will come out of the pockets of every ratepayer in London we think that he should hand over a very substantial proportion of it to the hospital, an institution which by its charity relieves the rates of heavy expenses which, were it not for the hospital, would have to be met by the ratepayers.

SIR ERNEST CASSEL'S GIFT FOR THE RELIEF OF OPHTHALMIA IN EGYPT.

IN the year 1902 Sir Ernest Cassel gave a sum of £40,000 the income of which was to be devoted to the treatment of sufferers in Egypt from diseases of the eye. It was decided by the authorities that the best way to carry out Sir E. Cassel's idea was to start a travelling ophthalmic hospital and this was accordingly done, the surgeon in charge being Mr. F. A. MacCallan. In common with other members of the medical profession we expressed it as our opinion that this scheme would not be successful and that the money would be more or less wasted. We were, however, apparently in error in this opinion, for Lord Cromer in his report on Egypt for the year 1904 says: "The experiment has proved a complete success. The generous donor of this money has every reason to be gratified with the very large amount of suffering which, in consequence of his liberality, has been relieved." The scheme has, however, been carried out upon a much larger scale than we were at first led to believe that it would be and the travelling tent has developed, according to Mr. MacCallan's report, into a large operating tent floored with concrete, two out-patient waiting tents, two in-patient tents, tents for the staff, and a kitchen. This equipment is, of course, much more like a small field hospital and we can well believe that it has done good service. Trachoma with its sequel trichiasis is the disease which has been most frequently treated and in all 3379 patients have been treated, while the number of operations performed has been 1268. Lord Cromer expresses a hope that before long the system will be extended, and judging by the report of the medical officer we think that this hope is quite justified.

THE PHYSIOLOGICAL ACTION OF VALERIAN JUICE.

M. Chevalier and M. Pichet, in a communication brought before the Société de Thérapeutique, and published in the Répertoire de Pharmacie for February, call attention to the physiological action of valerian juice prepared by expression of the fresh root out of contact with air, and of such a strength that one part of the juice represents one part of the root. They find that the juice diminishes the blood pressure and slows the pulse after a transient acceleration without increasing the work of the heart. This action is constant and serves to distinguish the fresh juice from preparations of valerian which are made from the dried root, as well as from the various valerianates used in medicine which have a slightly stimulating action on the central nervous system. This is due to a change in the physiological properties of the active constituents of valerian owing to oxidation during the process of drying. The sedative and antispasmodic action of the fresh juice of valerian root is very constant and is not accompanied by any permanent stimulating action. The results obtained by the writers occasion no surprise, as it is a well-known fact that the active principles of the plant undergo a chemical change which commences at the moment of collection. Collectors of herbs are familiar with the fact that a freshly gathered valerian plant has scarcely any odour, but by the time the collector reaches his destination the characteristic odour of the plant will have become well marked. Cats, as everybody knows, are particularly fond of valerian root and the more the root is bruised the more they are attracted by it. The chemical change is attributed to bornyl isovalerianate, a constituent of the fresh root, which during the process of drying gradually decomposes, producing free isovalerianic acid. Valerian root contains about 1 per cent. of a volatile oil, one of the constituents of which is the substance bornyl isovalerianate. In describing the physiological action of the volatile oil Sir Lauder Brunton[1] states that "the oil in large doses paralyses both the brain and spinal cord, lowers the blood pressure, and slows the pulse. It is employed as an antispasmodic and stimulant in cases of hysteria....... Valerianate of zinc has been supposed to combine the nervine tonic action of zinc with the antispasmodic action of valerian, but it is much better to use valerian itself or its oil along with a salt of zinc as the acid has no important physiological action." Since the fresh juice owes its peculiar physiological properties to the undecomposed bornyl isovalerianate contained in the volatile oil, it would appear to be more desirable to use the volatile oil in preference to the fresh juice and other preparations of valerian. The volatile oil can be distilled in quantity, so that a plentiful supply could always be obtainable, but some difficulty would be found in procuring at all times a supply of the fresh juice.

THE NEW SYDENHAM SOCIETY.

THE council of the New Sydenham Society announces some important additions to the attractions offered to its members. In future all members, new as well as old, will, on payment of the year's subscription, be entitled to choose one volume from the surplus stock. This will be without further payment and will be wholly additional to works issued for the year. Part of the society's library has for long been out of print. There remains in hand, however, to be selected from a long series of works, many of them of great permanent value. Amongst these may be mentioned: Laveran on "Paludism and its Organism"; Pierre Marie on "Diseases of the Spinal Cord"; Bernutz and Goupil on "Diseases of Women"; Trousseau's "Clinical Medicine," Vols. III. and IV; Niemeyer's "Lectures on Pulmonary Consumption"; Charcot's Lectures, several volumes; Billroth's "Surgical Pathology," two volumes; Guttmann's "Manual of Practical Diagnosis"; Koch on "Wound Infection"; Hirsch on "Geographical and Historical Pathology," three volumes; Graves's "Clinical Medicine," two volumes; Henoch's "Diseases of Children," two volumes; Ewald's "Disorders of Digestion," two volumes; Pozzi's "Gynecology," three volumes; Helferich on "Fractures and Dislocations"; several volumes of selected Clinical Lectures, Spiegelberg's Midwifery, two volumes, Naunyn's Cholelithiasis, and so on. In the case of a subscriber wishing for a work of more than one volume the payment of one or more subscriptions in advance will enable him to secure all at once. The council proposes to keep back a certain small number of all the volumes for future needs and the advantages now offered will, of course, cease in the case of each work when that minimum is reached. The number at present in hand varies greatly in different works and as regards some of the most valued may soon be exhausted. Under another regulation the council now allows members to select any seven of the society's volumes for a single guinea. In order to meet the increasing demands of the office and to secure more punctuality in the discharge of its duties the council has appointed Dr. Alfred E. Russell of 9, Wimpole-street, London, W., as acting general secretary, to whom in future all letters of inquiry should be addressed. Mr. Jonathan Hutchinson will for a time retain the position of honorary general secretary. The preparation of the Clinical Atlas remains in the hands of a large representative committee and the society's agency is, as heretofore, at Messrs. Lewis's, 136, Gower-street, London, W.

ALIEN AND IMMIGRANT LONDON IN 1781.

PRIOR to the year 1801 no census of the population of London had been taken but instructive conjectures as to the causes of death and the "chance of life" had been made since Graunt's "Observations on the Bills of Mortality," 1696. In 1781 Dr. Robert Bland drew some conclusions of this kind, as well as others, from the "Midwifery Reports of the Westminster General Dispensary" which are of no small interest to-day. The women admitted to the dispensary were asked to register their birthplaces and those of their husbands and from these facts, meagre enough in themselves, Dr. Bland constructed a comparative table of the population of London, in which it is set forth that of 3236 married persons accounted for at the Westminster General Dispensary only 824, or one-fourth, were native Londoners. Of the remainder four-sevenths, or 1870, were immigrants from the different counties of England and Wales; 209, or 1 in 15, came from Scotland; and 280, or 1 in 11, from Ireland. 53, or 1 in 60, were what we now call "aliens." Of 824 married persons born in London there were one-fifth more women than men. "This may be accounted for either by supposing a greater number of males to die or to migrate before they attain a marriageable age than women. It is also to be observed that of the Scotch and of the foreigners the women are in proportion to the men as about 1 to 33 but of the Irish they are as 3 to 7." If these statistics are to be trusted they throw light not only on the present alien question but on that of the origin of the Cockney proper. If three-quarters of the ancestry of native Londoners were immigrants, the theory recently advanced that Londoners cannot count three generations of Cockney ancestors is greatly strengthened. It should be borne in mind that the population of London was in 1781 far below 1,000,000. Putting it at about 750,000 and supposing that Dr. Bland's estimate of 1 foreigner in 60 be correct we may suppose that the total number of aliens proper residing in London in 1781 amounted to about 12,500.

INSTRUCTIONS TO MIDWIVES.

THE Manchester midwives supervising committee has issued a booklet of instructions to the midwives practising in the district under its supervision in which it reminds them of the obligations which rest upon them and which they are required to fulfil on pain of being reported to the Central Midwives Board and perhaps of being removed from the roll. As the committee points out, the Act is now in full force and after April 1st last no woman must use the title of midwife or its equivalent unless she is certified, nor may a woman certified under the Act employ any uncertified woman as her substitute. Instructions are given to the midwives as to the cleanliness of their persons and their homes. In order to insure the good sanitary condition of the latter arrangements have been made by which the midwife can have her house inspected by the sanitary authority if necessary. The committee recommends that the midwife's bag should have a removeable washable lining; for the purpose of vaginal douching it advises the use of lysol or kresol and for the disinfection of the hands a solution of perchloride of mercury of the strength of 1 in 1000. No doubt the question of expense prevented the committee recommending soluble biniodide of mercury for the latter purpose, as otherwise it is a much better disinfectant than perchloride of mercury with the great advantage of not spoiling instruments. The midwife is carefully instructed how to keep her appliances clean and also the bag itself, a most important precaution, and one which, we fear, is often neglected. In the preparation of her hands great stress is laid on the importance of a proper scrubbing with soap and water and a nail brush and then washing the hands in a solution of perchloride of mercury of the strength of 1 in 1000 for at least two minutes. We are glad to see that the committee recommends that a pad of wool wrung out of the same solution should be applied to the vulva after the delivery of the placenta. Further instructions are given with regard to the care of the mother during the lying-in period and of the newly born child. Rules are also laid down to guide the conduct of the midwife with regard to the notification of the birth of stillborn children, the death of a mother or child before the arrival of medical assistance, and the calling in of medical assistance. Finally, there are very clear instructions as to the precautions to be taken by the midwife when she has had the misfortune to be in attendance on a case of puerperal infection. This little book should prove of great service to the women for whom it is intended and we hope that other supervising committees will follow the excellent example of the Manchester committee in issuing similar rules.

PERITONITIS IN TYPHOID FEVER WITHOUT PERFORATION.

IT is well known that peritonitis in typhoid fever may result from other causes than perforation of the intestine, such as ulceration of the gall-bladder or rupture of a suppurating mesenteric gland or of a splenic abscess or without any local cause. Dr. J. Dreschfeld states in Allbutt's "System of Medicine" that peritonitis may be due to extension of inflammation to the serous coat of the intestine and that it then generally is circumscribed and tends to form adhesions but occasionally gives rise to local suppuration. At the meeting of the Société Médicale des Hôpitaux of Paris on March 17th M. Courtois-Suffit and M. Beaufumé contributed an important paper and reported the following case of peritonitis without any definite local cause. It is noteworthy because the peritonitis was not circumscribed but general. A youth, aged 18 years, was admitted into hospital on Feb. 3rd, 1905, the eleventh day of an attack of typhoid fever. The temperature was 104·3° F. All the usual symptoms were present and the Widal reaction was obtained. He was treated by cold baths (at 61° F.) which were given every three hours. The temperature remained about 104°. On the twenty-first day the pulse was 114, no pain was complained of, and the baths were given as usual. Suddenly at 11.30 P.M. the patient complained of violent pain in the upper part of the left iliac fossa. After about ten minutes the pain radiated over the whole abdomen; after half an hour a liquid stool was passed and after another quarter of an hour another stool. There was no tympanites, the pulse was 110 and feeble, the face which previously had been congested became very pale, and the respiration became noisy and panting. Ice was applied to the abdomen and the pain and oppression rapidly disappeared. At 1 A.M. the temperature was 103·7°. At 1.30 A.M. he hiccoughed and vomited greenish-yellow fluid. At three the temperature was 104·9° and there was no pain. The patient slept until 5.30. At six the temperature was 106·1°. At eight one of the writers arrived at the hospital.

He was struck with the pallor of the patient's face; the features were drawn, the eyes were surrounded with dark circles, the nose was cold, the tongue was dry, the pulse was 114 and feeble, the abdomen was scarcely sensitive and was not tympanitic, there was no dulness in the flanks or hypogastrium, and the liver dulness was preserved. In spite of the absence of tympanites intestinal perforation was diagnosed and laparotomy was performed at once. On opening the abdomen no gas escaped but about one and a half litres of brownish-yellow odourless fluid containing whitish particles. The intestinal coils were not distended but very congested and agglutinated by yellowish-white friable membranes, especially on the right side. The small and large intestines were examined throughout their whole length and showed no sign of perforation; the appendix was quite normal. The mesentery contained numerous large glands but none of them were ulcerated. The wound was closed and drainage was provided. After the operation the patient was somnolent. About 3 P.M. he called for the bed-pan. He passed about a pint of red fluid, became collapsed, and died. At the necropsy about a pint of yellowish-brown fluid was found in the pelvis. The lower third of the ileum and the ascending colon were much congested. The intestines were covered with yellowish-white lymph which was abundant for a distance of six feet above the ileo-cæcal valve and on the cæcum and ascending colon. Water was injected into the intestines but no perforation was disclosed. A large quantity of blood escaped from the open end, indicating an intestinal hæmorrhage which seemed to have come from a large ulcerated Peyer's patch. There were numerous typhoid ulcers in the ileum, cæcum, and ascending colon. The appendix was perfectly sound. No lesion to account for the peritonitis was found in any viscus. Dieulafoy[1] explains such cases of peritonitis as due to typhoid infection independent of intestinal infection, the peritoneum being infected in the same manner as the pleura or the bones. M. Courtois-Suffit and M. Beaufumé think that it is more logical to suppose that the peritonitis is due to infection by contiguity from the intestines. This mode of infection is indicated in their case by the predominance of membrane at the end of the ileum and the beginning of the colon where the typhoid lesions were greatest. The symptomatology of the peritonitis is in several ways remarkable. The onset by sudden and violent pain exactly resembles that of perforative peritonitis but the lesions found on operating at the end of ten hours show that the peritonitis must have existed for a much longer period. Therefore it must have remained completely latent for a long time. It is also noteworthy that the symptoms of perforative peritonitis—diffuse abdominal pain, vomiting, hiccough, and so on—were present with one important exception: there was no tympanites and the liver dulness was preserved. The absence of perforation readily explains these facts.

PLAGUE AND RATS.

OUTBREAKS of bubonic plague have occurred at intervals in Sydney during the last few years but without ever attaining very extensive proportions. At an early period in the history of these invasions—namely, in the year 1900, Dr. J. Ashburton Thompson, president of the Board of Health of New South Wales, expressed the opinion that epidemic plague in the human subject was due wholly to plague-infected rats and on the successive appearances of the disease in the colony the work of his department in checking it has been directed mainly to the destruction of rats. The second outbreak of plague in Sydney came to an end in June, 1901, the last patient being attacked about the 12th of that month and the last plague-infected rat was caught on July 14th. The rat-catchers still continued at work and from July 14th, 1902, to April 30th, 1903, there were caught 31,075 rats and mice, of which 17,160 were examined in the laboratory but were found free from plague. Sydney had therefore for eight months and a half been free from plague either in rodents or man. On May 12th, 1903, a plague-infected rat was found. During the period from May 1st to August 15th 8695 rats and 5976 mice were examined in the laboratory and of this number 111 rats and 50 mice were ascertained to be infected with plague. The last plague rodent was brought in on August 15th. In the course of this same period two cases (both terminating in recovery) occurred in the human subject, one being notified on June 20th and the other on July 4th. In commenting on these facts Dr. Thompson directs attention to the extremely small proportion borne by the plague-infected rodents to the total number caught and he explains this partly on the ground that, as a rule, those which are taken in traps are in good health and actively searching for food, or, if infected, have not reached a stage of illness at which pathological signs have appeared. Further evidence tending to show the causal connexion between plague in rats and man is given in the *Australasian Medical Gazette* of Feb. 20th, the article in question being an account of the first outbreak of plague in New South Wales outside Sydney. Between Dec. 14th, 1904, and Jan. 1st, 1905, six persons were attacked with sudden illness at four farms within moderate distances of Ulmarra, a village on the Clarence river. Communication between the Clarence river district and other parts of the State is chiefly by sea and a regular trade is carried on by sea with Brisbane, in Queensland. Four of these six patients died and the diagnosis of plague was made about Jan. 2nd. A number of plague-infected rats were caught in Ulmarra and the neighbourhood between Jan. 8th and the end of the month. Six more patients were attacked between Jan. 7th and 27th. At one house, which yielded two cases, plague-infected rats were identified immediately before the patients fell ill.

NEW LYING-IN HOSPITAL AT WOOLWICH AND THE HIGHER TRAINING OF MIDWIVES.

AT Woolwich on May 11th Princess Christian opened a "Home for Mothers and Babies and Training School for District Midwives," which has been established by the efforts of Miss Alice Gregory, a daughter of the Dean of St. Paul's, and herself a trained and certified midwife, assisted by a committee of which Mr. F. S. Hawkes is honorary secretary. The home contains 12 beds and its staff is to consist of three certified midwives who have passed the examination of the Obstetrical Society of London and have had a training also in general nursing. The local medical practitioners will attend when summoned and there is a consulting staff (consisting of Dr. A. L. Galabin, Miss Annie McCall, M.D. Bern, and Mr. G. Bellingham Smith) whose services will be available if any exceptional difficulty should arise. The opening ceremony consisted of a short service of prayer, conducted by the vicar of the parish, the Rev. W. H. Carey, concluding with a benediction by the Dean of St. Paul's. Princess Christian then declared the home open and wished it every success. In proposing a vote of thanks to Her Royal Highness Dr. C. J. Cullingworth said that in addition to the benefits which this hospital would confer upon the densely populated district of Woolwich Miss Gregory and those associated with her had decided to give it a character of its own as a training school for midwives. The weak points of the ordinary training of a midwife in this country were: (1) its short duration; (2) its non-insistence upon a previous hospital training in general nursing; and (3) the absence of any organisation for keeping the pupils in touch with their school after they have left it. It was intended in the scheme that day inaugurated to obviate all these defects. It was also an essential part of the scheme that every pupil who entered for training should undertake to devote herself to district midwifery—i.e., to work amongst the poorer classes of the community, the classes whom the Midwives Act was intended to benefit. This was to be the distinguishing feature of that school. On the other hand, the majority of the pupils at the existing training schools did not contemplate devoting themselves to district work, their main object being to qualify themselves as high-class monthly nurses. Until the hospital was in a position to offer a free training a fee of £20 would be charged for a course of from six to twelve months and it was hoped that "scholarships" to this amount would be instituted by various county councils.

---

[1] Manuel de Pathologie Interne, tome iv., p. 130.

ANEURYSM OF THE AORTA SIMULATING POTT'S DISEASE.

WHEN aortic aneurysm causes erosion of the vertebræ death usually occurs before the process has progressed sufficiently to cause spinal symptoms or spinal deformity. If an aneurysm is so situated as to develop without producing characteristic symptoms and lays bare the spinal membranes, producing compression myelitis, Pott's disease or a tumour may easily be diagnosed. In the University of Pennsylvania Medical Bulletin Dr. C. W. Burr has reported the following remarkable case in which this error occurred. A man, aged 56 years, was admitted into hospital on Oct. 15th, 1902. He stated that many years before he had syphilis and also malarial fever. His present illness began with dull rheumatic pains in the back four years before admission. After a time the left leg and then the right became numb. Later the legs became stiff but he was able to walk until two days before admission. Two weeks before admission incontinence of urine began. He lay in bed with the legs rigidly flexed on the thighs and the thighs on the abdomen. The knee-jerks were much increased and ankle clonus was present on both sides. There was only partial control of the bladder and the rectum. At the eighth dorsal vertebra slight angular curvature was observed and pressure on the spine was painful. The patient complained of pain under the right scapula. The right leg was anæsthetic; the left was sensitive to deep pressure but not to touch. Below the iliac crests there was complete tactile anæsthesia. The urine was alkaline and contained a little pus and a trace of albumin. The temperature ranged from 98° to 100° F. Examination of the chest was negative. A tuberculin injection gave a distinct reaction. The diagnosis of Pott's disease seemed clear. Bed-sores formed on the buttocks and death took place on March 23rd, 1903. At the necropsy marked bulging of the thorax posteriorly on the left side was observed. A large aneurysm extended from the descending portion of the arch of the aorta to the tenth dorsal vertebra. The bodies of the dorsal vertebræ from the fourth to the tenth inclusive were completely eroded and the spinal canal was exposed. The spinal dura mater was adherent to the posterior wall of the aneurysm for this distance. The left pleural cavity was filled with blood which had come from a rupture of the aneurysm. No signs of tuberculosis were found. Microscopic examination showed proliferating internal and external pachymeningitis of the dorsal cord and ascending and descending degeneration. Dr. Burr was led into error by the slight pain, the marked kyphosis, the tuberculin reaction, and the fact that the symptoms were entirely spinal. If he had continued to examine the patient's back at intervals he could have finally made a correct diagnosis because such bulging of the ribs as was found at the necropsy never occurs in Pott's disease. But this bulging must have developed only a short time before death because Dr. Burr ceased to examine the patient only when he was sure that propping him up in bed for the purpose would be injurious. Dr. Burr also thinks that he ought to have given more thought to the long period which elapsed before nerve symptoms occurred, as such is very rare in Pott's disease.

THE QUEEN'S JUBILEE HOSPITAL.

IN THE LANCET of April 22nd we referred to the position at the above-mentioned hospital and gave the salient points of the report of the Commissioners appointed by King Edward's Hospital Fund. This report practically recommended that a clean sweep should be made of the present staff and board of the hospital with the exception of the treasurer and the trustees and suggested that the hospital should be transformed into a casualty and out-patient institution. The board has issued a reply suggesting a modification of the Commissioners' recommendations on the following lines:—

> (1) That the hospital continue to exist as a general hospital for in- and out-patients; (2) that the constitution and by-laws be suspended for a period of 12 months; (3) that the present honorary medical staff be retained; (4) that the present board of management resign; (5) that a temporary board of management be formed to serve for one year and then to report to the governors; (6) that one-half of the lay members of the new temporary board be elected by the governors and the other half by the executive of the King's Fund; (7) that the chairman be nominated by the executive of the King's Fund; (8) that the medical staff in addition elect representatives from their own body to serve on the board, to assist and advise on matters relating to the medical department; (9) that a competent male secretary be appointed forthwith.

These modifications, it will be seen, differ mainly from those of the King Edward's Fund Commissioners in the retention of the medical staff and of the hospital as a hospital, and an agreement may be arrived at which will eventually lead to a permanent peace. In our opinion the hospital is not required as a hospital and we cordially agree with the Commissioners, who think that it should be reconstituted "as a casualty and out-patient department with a few beds attached."

THE ACTION OF A NEW COLLOIDAL FERRIC HYDRATE (DIALYSED IRON) ON ALBUMIN.

M. J. Tribot and M. H. Chrétien have brought to the notice of the Académie des Sciences [1] a new form of dialysed iron which they find possesses in a greater degree the power of transforming albumin into albumose than does the ordinary dialysed iron. The latter was discovered by Graham and has been used extensively in medicine but owing to the method of preparation it contains a notable proportion of ferric chloride in addition to the colloidal ferric hydrate. M. Tribot and M. Chrétien successfully tried to obtain a solution of dialysed iron containing less ferric chloride by passing an electric current of about one ampère through the ferric solution during the process of dialysis. The solution of dialysed iron so obtained possesses all the properties of Graham's solution and experiments carried out to compare the action of the two liquids on albumin demonstrated the advantage of the electro-dialytic solution over Graham's solution. The solutions were made alkaline with potassium hydrate and added to a known weight of albumin; the yield of albumose was observed after heating during four hours at from 40° to 42° C. The electro-dialytically prepared solution converted 27·02 per cent. of the albumin into albumose, while Graham's solution only converted 8·16 per cent. of the albumin. When the iron solutions were acidified with hydrochloric acid slightly lower figures were obtained. In all cases no peptones were formed. M. Tribot and M. Chrétien are continuing their researches but from the results which they have so far obtained it would appear that already an improvement has been made in this important preparation of iron. It is well known that metals are absorbed from the intestinal canal in the form of albuminates and the ferric salts have an irritant action in the stomach. A solution of ferric hydrate practically free from chloride might, therefore, be expected to be absorbed with greater ease than is the case with the ordinary dialysed iron. Further results, especially those of a clinical nature, will be awaited with interest.

[1] Comptes Rendus, Jan. 16th, 1905.

THE MEDICAL SCHOOL OF WESTMINSTER HOSPITAL.

IN obedience to the view that the concentration of the teaching of the preliminary and intermediate subjects of the medical curriculum in London at a few centres will result in greater efficiency in teaching as well as economy in expenditure, the Westminster Hospital Medical School has completed negotiations with King's College by which arrangements have been made for the teaching of physics, chemistry, anatomy, physiology, and materia medica (that is to say, the subjects of the preliminary and intermediate examinations) to Westminster Hospital students at King's College. Students will enter Westminster Hospital Medical School, as in the past, and will remain Westminster Hospital men and will not become matriculated students of King's College, but they will be taught the earlier subjects of study at that institution. The scheme will come into effect at the commencement of the next winter session in October. At the same time the Westminster Hospital Medical School is thoroughly re-organising the teaching of the subjects of the final examination. Those responsible for this important move believe that their action marks the commencement of a more general concentration of the teaching of the preliminary and intermediate subjects of the curriculum and that such concentration will promote the best interests of medical education in London. Different aspects of the question are discussed this week in our columns by Mr. Henry Morris, whose oration at the Medical Society deals with the subject, and by ourselves in a leading article.

THE ANNUAL DINNER OF THE PHARMACEUTICAL SOCIETY.

THE members of the Pharmaceutical Society and their friends must have been encouraged and gratified at the annual dinner held in the Whitehall Rooms of the Hôtel Métropole, London, on May 16th by the vigorous speeches which were delivered in support of the amended Pharmacy Bill now before Parliament. The position created by the judgment of the House of Lords to the effect that the word "person" in the 15th Section of the Pharmacy Act could not apply to "a company of persons" is undoubtedly serious for the pharmacist and is a menace alike to the dignity of the pharmaceutical calling and to the health of the public. It seems illogical to lay down that the 15th Section of the Act cannot apply to a limited liability company because they are not persons who can be examined for the purpose of qualification and are not individuals. Such an interpretation defeats the intention of the Act, for surely those who were responsible for the drafting of the Bill intended to apply its restrictive clauses to anyone who desired to act as a pharmacist—i.e., to a company of persons as well as to a single person. If such was not the intention then the sooner the Pharmacy Act is amended the better for all concerned. Company-mongering is an undesirable and a dangerous association with the profession of pharmacy. It has been said that pharmacists have themselves to thank owing to the heavy charges made by them in the past for medicines and the making up of prescriptions. If they had been content to make moderate and reasonable charges there would have been, it is urged, no field for company pharmacy and no opportunity for the mere company promoter. Whether that be the case or not this kind of argument forms in the mind of the limited liability company a justification for its existence, and in one instance it was announced in an advertisement in the *Times* that after independent investigation that newspaper had declared that the money saved by the public who dealt with drug stores amounted to no less than a million sterling per annum. In proposing the toast of "The Houses of Parliament," the President of the Pharmaceutical Society, Alderman R. B. Robinson, J.P., L.C.C., said that he had had a communication from the editor of the *Times*, in which the latter stated that the *Times* had made no independent investigation of the kind suggested and no estimate of the amount saved by the public, but the statement appeared in an advertisement the accuracy of which was in no way guaranteed by the *Times*. The chief topic of the evening was thus, as might have been anticipated, the amended Pharmacy Bill and amongst those who spoke in favour of the reform suggested were Mr. T. Lough, M.P., Mr. Henniker-Heaton, M.P., Sir R. Douglas Powell, and Mr. David Howard. The last-named gentleman paid a well-deserved tribute to the excellent work done by the Pharmaceutical Society and the President, in replying to the toast of the society, stated that its membership was steadily increasing and that the benevolent fund had afforded aid to the extent of £3000 to its less fortunate members. In response to the toast "The Medical Profession," Sir R. Douglas Powell referred to the importance of the making up of medicine being consigned only to a skilled person. The President, in proposing the toast, touched upon the excellent relations subsisting between the medical profession and pharmacists and mentioned that owing to the representation of medical men they had obtained an extension of the poisons schedule so as to include substances such as sulphonal.

GASTRITIS WITH EROSIONS, OR "EROSIVE GASTRITIS."

IN the Proceedings of the Pathological Society of Philadelphia for January last Dr. John Funke records his investigation of a case of parenchymatous nephritis in which extensive erosions of the stomach were found at the post-mortem examination. His paper includes a summary of the chief views on the origin and the nature of gastric erosions. The condition found in the stomach consisted in a number of small depressed areas along the lesser curvature towards the cardia, around the pylorus, and on the greater curvature near the pylorus. These areas were round, oval, or irregular in outline, varied from a millimetre to a centimetre in diameter and from one to two and a half millimetres in depth, their edges were bevelled, and the floor was usually pale and smooth. As a rule they were discrete but in a few cases two had coalesced. They were more abundantly found between the folds of the mucous membrane than upon them. On histological examination the erosions were found in some cases to involve about half the thickness of the mucosa, while in a few they extended nearly to the *muscularis mucosæ*. Over most of the erosions there was a layer of necrotic tissue containing many lymphoid cells, while in one case a partially separated slough was found. The gland tubules in the floor of the erosions contained degenerated cells, while the lining epithelium frequently showed mitotic figures; the retiform tissue between the tubules was infiltrated with mononuclear and a few polymorphonuclear leucocytes, while the vessels were engorged. These changes Dr. Funke regards as indicating inflammation and he calls the condition "erosive gastritis," although it would be more conveniently and more correctly termed gastritis with

I add a copy of another analysis made by the Royal Technical Institute of Florence:—

Physical characters: The liquid is colourless, slightly opaline on account of finely divided solid matter held in suspension and the large number of micro-organisms. Odour very faint, almost imperceptible. Specific gravity at 15° = 1002. Reaction, slightly alkaline Substances held in solution: iron, lime, magnesium, potassium, sodium, silicic acid, sulphuric acid, hydrochloric acid, phosphoric acid, ammonia, and traces of nitrogenous organic matter. Tests for nitrates, nitrites, and sulphuretted hydrogen gave negative results. A test to determine the quantities gave the following results: Matter in suspension = 0·067 per litre; residue at 100° = 3·126 per litre; ash = 0·3448 per litre; chloride = 0·1603 per litre; organic nitrogen = 0·302 per litre; nitrogen as ammonia = 0·11 per litre; total nitrogen = 0·412 per litre. From the results of these analyses the said liquid taken from the bacteriological cesspool in Via Aretina, N. 6, may without risk be discharged into the city drains.

And a third analysis made by Professor Ubaldo Mussi of Florence:

Specific gravity, 1002; reaction, slightly alkaline; colour, pale amber yellow; odour, almost imperceptible and not disagreeable, after a short exposure to the air it disappears entirely; appearance, opalescent; ammonia, present in small quantity; nitrites, none; nitrates, none; organic matter, 0·0016 per cent.; alcohol, none; albuminous substances, none; urea, none; lime, traces; chlorides, traces; sulphates, traces; phosphates, none. In the sediment obtained by centrifugal process several paramecium coli were found, some non-characteristic, and therefore indefinable, detritus. The opalescence of the liquid is due to the paramecium; on standing a short time it becomes quite clear—i e., on the death of the paramecium whose life in the liquid is of very short duration. In conclusion, the component parts of the fæces, including the urine, contained in the cesspool in Lung'Arno Guicciardini N. 11, subjected to treatment by the Montgomerie Neilson system, are totally decomposed and transformed, and the liquid produced is, in its chemical composition, very different from sewage and presents rather the physical characters of inferior drinking water, hence its discharge into the sewers is perfectly harmless.
